INTERNATIONAL INSTITUTE FOR POPULATION SCIENCES

Vision: “To position IIPS as a premier teaching and research institution in population sciences responsive to emerging national and global needs based on values of inclusion, sensitivity and rights protection.”

Mission: “The Institute will strive to be a centre of excellence on population, health and development issues through high quality education, teaching and research. This will be achieved by (a) creating competent professionals, (b) generating and disseminating scientific knowledge and evidence, (c) collaboration and exchange of knowledge, and (d) advocacy and awareness.”

Preface and Acknowledgements

The District Level Household and Facility Survey-4 (DLHS-4) is a nationwide survey covering 640 districts from 36 States and Union Territories of India. This is the fourth round of the district level household survey which was conducted during 2012-13. The Survey was funded by the Ministry of Health and Family Welfare, Government of India.

At the outset, we acknowledge our sincere gratitude to the Ministry of Health & Family Welfare, Government of India for designating the International Institute for Population Sciences (IIPS) as the nodal agency for conducting District Level Household and Facility Survey-4 (DLHS-4). We would also like to take this opportunity to acknowledge Shri. Bhanu Pratap Sharma, Secretary-Ministry of Health and Family Welfare (MoHFW), Government of India for his advice, suggestions and support. Our special thanks are due to Shri. Lov Verma and Shri. Keshav Desiraju former Secretaries, Ministry of Health and Family Welfare (MoHFW), Government of India, for providing overall guidance and support extended to the project. We gratefully acknowledge the active involvement, assistance, help, co-operation and suggestions received time to time from Shri. C.R.K. Nair, Additional Director General, Dr. Rattan Chand, Chief Director and Shri. Biswajit Das, Director-Statistics Division, Ministry of Health and Family Welfare, Government of India. We also extend our thanks to Smt. Madhu Bala, former Additional Director General and Shri Rajesh Bhatia, former Director-Statistics Division, Ministry of Health and Family Welfare, Government of India for their support from time to time.

We gratefully acknowledge the NIHFW, New Delhi, especially Dr. M. M. Misro, Dr. T. G. Srivastava and Dr. Kalpna, for their immense help, assistance, support and coordination with all Partner Institutes to bring out quality DBS results/data. We also acknowledge our sincere gratitude to all Partner Institutes for providing training and support of CAB components and bringing out the quality DBS results.

We sincerely extend our appreciation to HLL Life Care Ltd., New Delhi, for procuring CAB equipments and consumables also supply chain to different states across the country.

Our special thanks are to all the members of Technical Advisory Committee of DLHS-4, particularly Dr. N. S. Shastry, Chairman, Former DG & CEO (NSSO), for their constant involvement and technical inputs and support at various stages of the survey.

We also gratefully acknowledge all members of Sub-Committee on Sampling especially Shri. G. C. Manna, Chairman, DDG, CSO, MoSPI for their technical support received from time to time.

Thanks are also due to Dr. Rajiv Mehta and Shri. A. K. Mehra, former Additional Director Generals at the National Sample Survey Organisations, Kolkata for providing UFS blocks.

We thank Dr. T. K. Roy, Former Director, IIPS, for reviewing the model report and for his useful suggestions.

This acknowledgement cannot be concluded without expressing appreciation for the efforts and hard work put in by the field investigators, supervisors, health investigators in collecting data and timely transferring data to IIPS.

Last but not the least, we are grateful and appreciate the efforts of all the respondents who participated and spared their valuable time with us by providing the required information.

DLHS-4 Coordinators
International Institute for Population Sciences

1. INTRODUCTION AND HOUSEHOLD CHARACTERISTICS

This state report of Mizoram pertains to the fourth round of District Level Household and Facility Survey (DLHS-4) 2012-13 following the preceding three rounds undertaken by the Ministry of Health and Family Welfare (MoHFW), Government of India (GoI). In the past (Round-I in 1998-99, Round-II in 2002-04, and Round-III in 2007-08) with the main objective to provide reproductive and child health related database at district level in India. The data from these surveys have been useful in setting the benchmarks and examining the progress the country after the implementation of RCH programme. In addition, the evidences generated by these surveys have been useful for the purpose of monitoring and evaluation of the ongoing programmes and the aspect of planning of suitable strategies by the central and state governments. In view of the completion of eight years of National Rural Health Mission (2005-12), that it was felt there was a need to focus on the achievements and improvements. The Ministry of Health and Family Welfare, Government of India, therefore initiated the process of conducting DLHS-4 and designated the International Institute for Population Sciences (IIPS) as the nodal agency to carry out the survey. MoHFW provided funds for implementation of DLHS-4, guided by a duly constituted Technical Advisory Committee (TAC).

The main objective of District Level Household and Facility Survey-4 (DLHS-4) is to provide maternal and child health care (MCH) indicators and prevalence of morbidity for a wide range of common, communicable, non-communicable and lifestyle diseases for the year 2012-13 covering the following aspects:

- Household basic amenities
- Prevalence of morbidity
- Coverage of ante-natal services and immunization services.
- Proportion of institutional/safe deliveries
- JSY Beneficiaries
- Economic burden of delivery
- Contraceptive prevalence rate
- ASHA's involvement
- Unmet need for family planning
- Awareness about RTI / STI and HIV / AIDS
- Infrastructure, manpower, equipments, drugs, services of public health facilities
- Linkage between health facility and MCH indicators

The bilingual questionnaires prepared in Mizo and English language pertaining to Household, Clinical, Anthropometric and Bio-Chemical tests (CAB) and Ever Married Women (age 15-49) were used and canvassed using Computer Assisted Personal Interviewing (CAPI). It was for the first time in the country that large scale demographic and health survey at the district level was successfully carried out by using Computer Assisted Personal Interviewing (CAPI) in DLHS-4. The CAPI software was developed by using MMIC (Multi-Mode Interviewing Capability) tool. Mini laptops were loaded with CAPI software and bilingual questionnaires and provided to the Field Agencies authorized to carry out the survey with the designated

states. Each team was provided four CAPIs/Mini laptops, one for each investigator. Supervisors were responsible for directly uploading the completed PSU's data to the IIPS, FTP server located in Mumbai on day-to-day basis. The use of CAPI optimized resources required for transferring the filled questionnaires from field to state office, data entry and received at IIPS. For the first time biomarkers were also used in DLHS-4. The village and health facility questionnaires were canvassed by using paper & pen method in DLHS-4. In the household questionnaire, information of all the members of the household and socio-economic characteristics of the household, possessed assets, number of marriages, morbidities and deaths in the household since January 2008, and also drinking water, toilet, drainage and kitchen facilities data were collected. The ever-married women questionnaire contained information on women's characteristics, maternal care, immunization and childcare, contraception and fertility preferences, reproductive health including knowledge about HIV/AIDS. The village questionnaire contained information on the availability of health, education and other facilities in the village, and whether the facilities are accessible throughout the year. The health facility questionnaire contained information on human resources, infrastructure, equipments, drugs and services. For the first time, a population-linked facility survey has been conducted in DLHS-4. At the district level, all Community Health Centres, Sub-Divisional Hospitals and District Hospitals were covered. Further, all Sub-Health Centres and Primary Health Centres which cater to the needs of the population of the selected PSUs were also covered. Fieldwork in Mizoram for the 8 districts was conducted during June 2013 to November 2013, gathering information from 8,583 households and 6,506 ever married women (15 to 49 years). Table 1.2 provides breakup of PSUs and households by district and rural urban residence.

2. SURVEY DESIGN

DLHS-4 is a district level survey and a multi-stage stratified designed adopted for selection of representative sample of each district in Mizoram. Rural and urban areas of a district are considered as natural strata. Wherever applicable, urban population in a district was further stratified into million class cities and non-million class cities. For the purpose of sampling of the urban samples, two-stage sampling was used where the primary sampling unit (PSU) is the NSSO urban frame survey (UFS) blocks and second stage sampling unit (SSU) is the household. The urban PSUs are selected by equal probability without replacement and ultimate stage sampling unit (USU) selected by process of circular systematic sampling. The allocation of PSUs to million and non-million class cities was proportional to relative sizes. Distribution of PSUs of a district is proportional to projected urban population of the district. For districts with less than projected 30 percent urban population, urban PSUs are oversampled. The sampling frame used for urban sampling is the town and city wise list of NSSO UFS blocks for 2007-08 provided by the SRD Unit of National Sample Survey Organisation (NSSO), Kolkata.

In rural areas of each district, sampling design is two-stage sampling with census villages as PSU and household as the second stage sampling unit (SSU). The PSUs are selected by PPS with replacement and SSU are selected by circular systematic sampling. Large selected PSU with more than 300 households are divided into at least three segments in such a way that

each segment has by and large the same number of households and two segments are then selected by SRS. List of villages in a district in Census 2001 are updated by removing villages of 2001 which have been designated as urban in 2007-08. NSSO UFS block list and this serves as the sampling frame for sampling of rural PSUs from a district.

Selection of rural health facilities in DLHS-4 is linked with the sampled rural PSUs. Primary Health Centres (PHC) and Sub-Health Centres (SHC) catered to the health care needs of the sampled rural PSUs were included in the Facility Survey (FS) of DLHS-4. All Community Health Centres (CHC), Sub-Divisional Hospitals and District Hospitals are covered under the Facility Survey of DLHS-4.

2.1. Sampling Weight

In generating district level demographic indicators, sample weight for household, women and children will be used. The weights for a particular district are based on three selection probabilities

f_1^i , f_2^i and f_3^i pertaining to i^{th} PSU of the district. These probabilities are defined as

$$f_1^i = \text{Probability of selection of } i^{\text{th}} \text{ PSU in a district} \\ = (n_r * H_i) / H,$$

Where n_r is the number of rural PSU to be selected in a district, H_i refers to the number of household in the i^{th} PSU and $H = \sum H_i$, total number of household in a district.

$$f_2^i = \text{Probability of selecting segment (s) from segmented PSU (in case the } i^{\text{th}} \text{ selected PSU is segmented)} = \frac{\text{(Number of segments selected after segmentation of PSU)}}{\text{(number of segment created a PSU)}}$$

The value of f_2^i is to be equal to one for un-segmented PSUs.

f_3^i = probability of selecting a household from the total listed households of a PSU or in segment(s) of a PSU

$$= (25 * HR_i) / HL_i$$

Where HR_i is the household response rate of the i^{th} sampled PSU and HL_i is the number of households listed in i^{th} PSU in a district.

For urban PSU, f_1^i is computed either as the ratio of number of UFS blocks included in the sample to the total number of UFS blocks of the district.

The probability of selecting a household from the district works out to be

$$f^i = f_1^i * f_2^i * f_3^i$$

The non-normalized weight for the i^{th} PSU of the district is, $w^i = 1/f^i$ while the normalized weight used in the generation of district indicators for the i^{th} district would be

$$= \frac{\sum_i n_i}{\sum_i n_i * w^i} * w^i$$

Where n_i is the number of households interviewed in the i^{th} PSU. The weight for women and children are computed in the similar manner considering corresponding response rate.

3. SURVEY INSTRUMENTS

The main instrument for collection of data in DLHS-4 was a set of structured questionnaires, namely, household, ever married woman, and village questionnaires as components of household survey. In the facility, separate questionnaires are used for Sub-Health Centre (SHC), Primary Health Centre (PHC), Community Health Centre (CHC), Sub-Divisional Hospital (SDH) and District Hospital (DH). Household and ever married women questionnaires are bilingual, with questions in both Mizo and English languages.

3.1 Household Questionnaire:- The household questionnaire starts with listing of all usual residents in each sample household including visitors who had stayed the night before the interview. The listing of usual resident members is used for identification of eligible respondents for ever married women and CAB (Clinical, Anthropometric and Biochemical) tests. For individual household member information on age, sex and marital status, relationship to the head of the household and education were collected. Marriages and deaths to members of household were also recorded. Efforts were made to get information about maternal deaths. Information were also collected on the main source of drinking water, type of toilet facility, source of lighting, type of cooking fuel, religion and caste of household head and ownership of durable goods in the household.

An added feature of household questionnaire of DLHS-4 is the collection of data on disability status, injury, acute and chronic illness for all members of the household.

Clinical, Anthropometric and Biochemical (CAB) tests: An important component of household questionnaire is the collection of biomarkers of eligible household members for the first time on a large scale demographic and health survey in the country at district level. This includes weight and height for all household members of age one month and above, Haemoglobin level for all household members aged 6 months and older, random blood sugar test and blood pressure measurements for all household members aged 18 years and above.

3.2 Ever Married Woman Questionnaire: - The respondents for the ever married woman's questionnaire are ever married women in 15-49 years of age living in the sampled households. Details on age, age at marriage, place of birth, educational attainment, number of biological children ever born and surviving by sex were collected. Accounts of ante-natal checks, experience of pregnancy related complications, place of delivery, delivery attendant and post-partum care, together with history of contraceptive use, sex preference of children and fertility intentions were recorded. For the recent births, immunizations status of children was collected either from the immunization card or asking the mother about the status of immunization of the child. The other information collected includes knowledge and awareness about RTI/STI and HIV/AIDS by source and treatment seeking behavior of RTI/STI.

3.3 Village Questionnaire: - This questionnaire was designed to collect information on availability and accessibility of education, health, transport and communication facilities at village level. Functioning of village committees and utilization of fund were additionally

collected from the sampled villages. Information relating to implementation and beneficiaries of various government programmes on girl child, maternal care, sanitation, food security, employment generation, and women's empowerment are also gathered as part of village information.

3.4 Facility Questionnaire :- In the facility survey, the information collected at the SHC level were availability of human resources, physical infrastructure, equipments and essential drugs and MCH service provided in one month preceding the survey. From the PHC, status of availability for 24x7 facility and services for delivery and new born care were collected. Additional information collected at PHC level were availability of Lady Medical Officer, functional Labour Room, Operation Theater, number of beds, drug storage facilities, waiting room for OPD, availability of RCH related equipments, essential drugs and essential laboratory testing facilities. Information that were collected for Community Health Centre (CHC) includes availability of 24X7 services for delivery and new born care, status of in-position clinical, supporting and Para-medical staff, availability of specialists trained for NSV (Non-Scalpel Vasectomy), emergency obstetric, MTP, new born care, treatment of RTI / STI, IMNCI, ECG etc. Physical infrastructure of CHC such as water supply, electricity, communication, waste disposal facilities, OT, Labour Room and availability of residential quarters for medical doctors were also collected in the facility survey. From the Sub-Divisional and District Hospitals status of availability of essential laboratory and ambulance services, emergency obstetric care service, availability of specialists, nurses, paramedics and technicians either on regular or contractual basis were collected in addition to infrastructure, provision for bio-medical and waste disposal and availability of residential quarters for doctors, nurses and staff. The mode of collection of information for health facilities is directly asking to the concerned officials, physical inspection and recording from relevant registers.

3.5 Sample Implementation

The field implementation starts with the preparation of location and layout maps of sampled PSUs in rural areas and obtaining map of sampled NSSO UFS blocks in urban areas. This is followed by preparation of list of households which served as the sampling frame for selection of representative households and it involved mapping and listing of structures and households for each sampled primary sampling unit (PSU) following the preparation of location and layout maps. The mapping and listing was carried out for each PSU by a team comprising of a mapper, a lister and a supervisor. A PSU in rural area is a village or part of a village or a group of small villages and it is NSSO UFS block in an urban area.

From the sampling frame of households prepared by mapping and listing, a sample of 28 households were selected by circular systematic sampling. Household and ever married women's questionnaires were canvassed by a team of 3 female and one male investigators, one supervisor and two health investigators were assigned for collection of CAB information. For quality assurance, field teams were monitored constantly by Project Officers, Officials of PRC, MoHFW, and Partner Institutes who facilitates DBS testing. Time to time DLHS-4 Project Coordinators of IIPS also made field visits to check and provide support to field teams.

4. DEMOGRAPHIC BACKGROUND OF MIZORAM

Basic demographic indicators of Mizoram and its districts as of Census 2011 are shown in table 1.1. The population of the state in Census 2011 is enumerated as 1,097 (in thousands). The decadal growth rate of the state during 2001-2011 is 23.48 percent. Decadal growth rate is highest in Mamit (37.56%) and lowest in Champhi district (16.65%) during this period. The sex ratio of the state is 975 females per 1000 males, it is 924 the lowest in Mamit and 1,009 the highest in the Aizawl. The overall literacy rate is 91.3 percent and the gender gap in literacy rate is 93.3 percent for males and 89.3 percent for females.

4.1 Sample Coverage

DLHS-4 surveyed a total of 320 primary sampling units (PSUs) covering 8,583 households with 95.8 percent response rate and 6,506 ever married women in reproductive age 15-49 years with 98.4 percent response rate. Table 1.2 shows the number of PSUs, households and ever married women interviewed and corresponding response rates by districts. Household response rate in the districts varies from 93.2 to 97.3 percents while that for the ever married women it is from 80.8 to 99.1 percents.

4.2 Village Facilities

Total number of PSUs surveyed in Mizoram 320 out of this 184 are rural PSUs. Most villages 95 percent have primary school in the village (Table 1.3). In 65.8 percent of the villages there is Sub- Health Centre (SHC) (Table 1.4a). Out of 184 villages, 81 percent of the villages have beneficiaries of ICDS, while 66.3 percent of the total villages have JSY beneficiaries but 21.2 percent villages have beneficiaries of JSSK (Table 1.4b). As can be seen from table 1.15 almost all sampled villages (94.6%) have anganwadi centre, 67.4 percent have accessed to any government health facility, but about 15.8 percent of the sampled villages have Primary Health Centre (PHC) and 69 percent of the villages have Village Health Nutrition and Sanitation Committee (VHNSC).

4.3 Household Amenities and Characteristics

As regards housing condition can be noted from table 1.6 (a), 15.7 percent of the surveyed households live in pucca houses, 20 percent in kachha houses and 53.3 percent in semi-pucca houses. As many as 89.7 percent of households have electricity connection, 45.5 percent of households use woods for cooking while 52 percent use LPG, 86.1 percent of households have mobile, 73.6 percent owned television, 3.1 percent owned bicycle while 20.3 percent owned motor cycle/ scooter and 10.2 owned car/jeep.

The sources of drinking water are shown in figure 1 and it is noted that 3.4 percent of households are using tube well or borehole water for drinking and 37 percent of households are using piped water into dwelling/yard/plot. As can be seen from figure 2 households which do not have access to improved clean toilet constitute 13.6 percent of the total surveyed households and only 70.2 percent of the households have access to improved flush/septic/pit toilets.

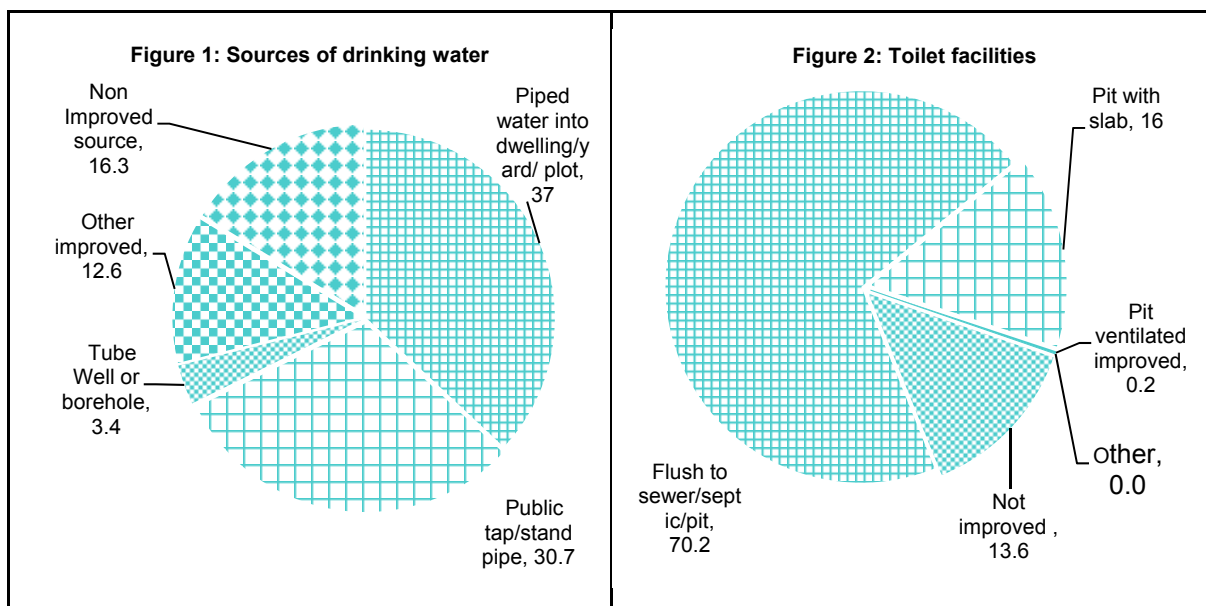

Table 1.6 (b) provides household access to electricity, drinking water, toilet and cooking gas and type of house by districts. The mean household size of the state is 4.5 while it is 4.5 in rural and 4.6 in urban (Table 1.7). One member households constitute 5.6 percent of all surveyed households, 81.8 percent household heads are male, median age of household members is 41 years. Christian is majority among households that is 87.6 percent and a highly significant share of 97.3 percent of the household heads are scheduled tribes (ST) and 0.5 percent of household heads are from the general caste.

The age-sex composition of the population of Mizoram is depicted in the population pyramid shown in figure 3. The pyramid is characterized by a shrinking base indicating declining trend in fertility, more females than males in 15-49 years and but not at older ages.

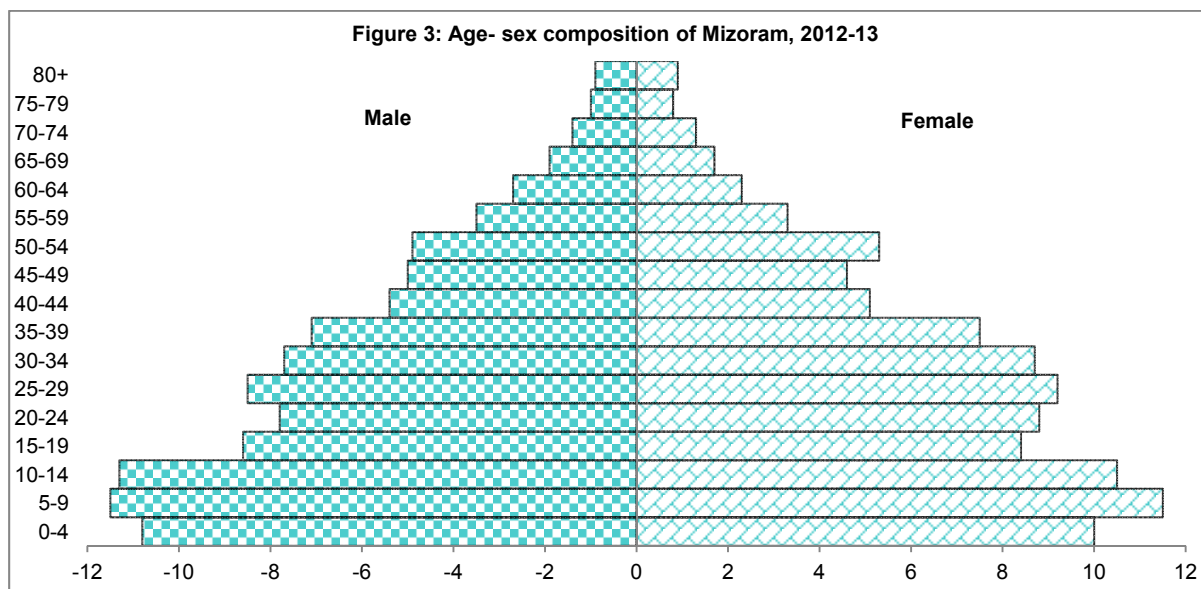

Table 1.8 provides differential in age-sex structures of rural and urban population of the state. As evident from table 1.9 there is sizeable proportion of unmarried males and females in 20-29 years and another distinctive feature is that are more widowed/divorced/separated among females than among males. The mean age at marriage for girls is 23.2 years while it is 26.1

years among boys. Mean age marriage for girls and boys by districts are shown in table 1.10. Six percent marriage among girls is below the legal age of 18 years and 14 percent of the boys got married below the legal age of 21 years. Tables 1.11 through 1.13 provide details about years of schooling of sampled household members by age, sex, caste and religion by rural-urban residence. Among females 7 years and older 2.1 percent are non-literate and corresponding figure among males is 1.1 percent. There is no sex differential in 11 or more years of schooling and the corresponding figures for male and female are 19 and 19.4 percent respectively. Regardless of sex individuals about 35.5 percent of the literate population has less than five years of schooling. The non-literate persons are less in urban than in rural and more persons have 11 or more years of schooling than among rural residents. Table 1.14 provides rate of current school attendance by age, residence, religion and caste.

Figure 4 shows the school attendance by age, 6-11 years and 12-17 years, the stage of primary and secondary education respectively and sex. The state achieved 98.3 percent school attendance among 6-11 years children and 91.9 percent among 12-17 years suggesting the existence of dropout at the secondary level. There is no evidence of significant sex differential in school attendance among 6-11 years and for 12-17 years.

5. CHARACTERISTICS OF WOMEN AND FERTILITY

Age at consummation of marriage is below 18 years for 17 percent of ever-married sampled women between 15-49 years irrespective of residence background. In rural, 23 percent of surveyed women reported their age at consummation of marriage below 18 years. In urban, 12 percent of surveyed women reported that they had started living with husband before reaching at age 18 years (Table 2.1). There are more non-literate women in rural (19.5%) than in urban areas (2.5 %). Non-literate husbands are less by 3.8 percentage points compared to non-literate wives/women in rural areas. Ten percent of women are non-literate whereas 31.6 percent of women are educated at least for 10 years. The proportion of husbands with 10 years or more schooling is 38.7 percent. Around 38 percent of the ever-married women were married for 15 years or more and the distribution of ever-married women in the categories of less than 5 years (20.6%), 5-9 years (21.2%) and 10-14 years (20.6%) marital duration are almost uniform with each less than twenty one percent each.

The proportion of women belonging to Christian has been highest and found to be 89 percent followed by (9.3%) Buddhist. The proportion of Christian women is higher in urban area (97.4%) as compared to rural (78%). The percent distribution of women by caste/tribes is

skewed towards Scheduled tribes (96.2%) followed by women belonging to ‘Others’ caste (1.9%) and Scheduled caste (1.1%). The percent of women who belong to Scheduled tribes is more (97%) in urban area than in the rural (95%).

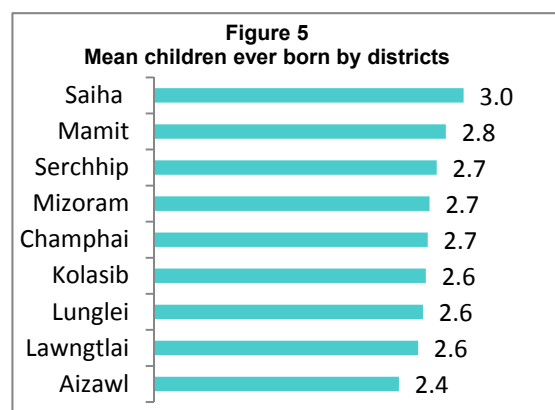

Table 2.2 shows the distribution of years of schooling among sampled women by background characteristics. The percentage of women who had 11 years or more schooling in the age groups are uniformly distributed while it is found to be low in early and older ages. In 25-29 years (15.2 %) and 30-34 years (15.3 %) is relatively higher than the other age groups. The urban women had 3.4 times higher percentage (19.2%) in education in the 11 more years of schooling as compared to rural women (5.6%). It is to be noted that at least 24.3 percent of women with 0-5 years of schooling and 13.2 percent of 6-8 years of schooling reported that their husband is non-literate.

5.1 Birth Order

Out of the total births since January 1, 2008 to ever-married women, around 52 percent births comes from urban area and the rest 48 percent from rural area. Around 35 percent of them belong to women in the age group 25-29 followed by 26 percent from women in the age group 20-24 (Table 2.3). The distribution of these births by religion shows that 90.5 percent births belong to Buddhist/Neo-Buddhist and rest belongs to other religions. The distribution of births by caste/tribes indicates that births from the Scheduled tribes contribute maximum 97 percent. Out of the total births since January 1, 2008 to ever-married women, 68.4 percent were of second or higher order births and the corresponding figures are 74.1 percent and 79.8 percent respectively for non-literate and women with less than 5 years of schooling (Table 2.3). The births of second and higher order are more in proportion among ever-married women aged 15-49 who are from rural area (73.4%), belonging to Hindu (73%), belonging to others category (81%), and among 40-45 years or older women (94%), compared to ever-married women educated at least up to 10 years (60.2%), and those belonging to scheduled caste (61%) (Table 2.3). Table 2.4 shows that the proportion of second and higher order births is the highest in Saiha district (74.7%) and the lowest in district Aizawl (65.4%). The proportion of first order birth has uniformly distributed among the districts. It ranges 25.3 percent in district Saiha to 34.6 percent in Aizawl. Over all percentage distribution of births is highest in district Saiha (16%) followed by Kolasib district (14%).

5.2 Mean Children Ever Born by Districts

Mean children ever born (CEB) to ever-married women aged 15-49 years is 2.7 with marginal differential by residence, while it is 3.1 for non-literate and 2.2 to women with at least 10 years of education. The completed fertility measured in terms of average children ever born to ever-married women aged 40-49 years is nearly 3.4. Mean children ever born to ever married women (15-49 years of age) is highest among the other backward classes (2.8%) and lowest in the scheduled caste (2.1). The differentials by religion have shown significant difference in

this fertility indicator. It is high among others religion (3.5) and low among Hindu (2.2). The state level estimates for mean children ever born by sex of children are also shown. It indicates that on average an excess of 0.1 male children to per female children ever born to ever-married women aged 15-49 years in the state as a whole. The sex differentials in mean children ever born to ever-married women aged 15-49 years is found to be higher for other backward classes, less than 5 years of education and early age women (age less than 20 years). In case of women 40-49 years, the sex differential in mean children ever born is measured as 0.1 children. In this age group of women, the gap between male and female mean children ever born to scheduled tribes (0.10), other caste (0.33), and less than 5 years educated women (0.12) is found to be much above than the state average (Table 2.5).

The mean children ever born to ever-married women by district is shown in figure 5, it varies from 3 children in Saiha district to 2.4 children in Aizawl district, while the state average is 2.7 children.

In Mizoram, most of the outcomes (97%) of pregnancies which occurred since January 1, 2008 to currently married women aged 15-49 years turned to be live birth. Only 1.4 percent of the pregnancies outcomes are reported as spontaneous abortion. Percentage of pregnancies that resulted in induced abortion is only 0.1 percent for the state as a whole. Age of women and sex composition of children depict less variation in the percentage of pregnancies resulted as induced abortion and spontaneous abortion. Percentage of pregnancies resulted into spontaneous abortions varies from nil in district Kolasib to 3.2 percent in Lawngtlai district. Still birth rate (5.9 %) is found to be highest in district Saiha. As a result 97 percent of pregnancies since January 1, 2008, the highest in the state, are reported as live births, (Table 2.7).

5.3 Fertility Intention and Sex Preferences for Additional Child

Fertility preferences of currently married women in terms of desire for an additional child, timing to have and preferred sex of desired additional child by number of living children are given in Table 2.8. Among those with no living children, around thirty seven percent women want a child soon (within the next two years) and 7.4 percent want a child two or more years later. Among the currently married women aged 15-49 with one living child, 13.8 percent wanted an additional child soon i.e. within two years. Most of the currently married women with two living children are either sterilized (26%) or undecided about children (28.4%). In addition, not more than 7 percent of women desired another child once they attain two or more surviving children.

Figure 6 depicts the fertility preference of all currently married women regardless of number of living children. Eight percent of currently married women want no more children, eight percent want additional child soon, nineteen percent is undecided about having an additional child and 37 percent have undergone sterilization. Eleven percent of currently women want to have an additional child but they have not taken any decision about timings when to have it.

Among the currently married women with no living children but want an additional child, 22.6 percent reported that sex of the child does not matter, 50.6 percent say it is up to God while 20.5 and 6.4 percent want to have an additional child as a boy and a girl respectively. Among those who had at least one living child and wanted to have another child, the percentage of women who were able to tell about preferred sex of additional child is quite high (23.4 % wanting boy and 21.9 % wanting girl). With increasing number of living children, longing for an additional male child becomes more and more magnified from 23.4 percent among currently married women with one child to 34.1 percent among currently married women with three living children. It is interesting to note that percentage of women with four and above living children reporting about preferred sex of additional child further increases in the response categories of doesn't matter and up to God (Table 2.8).

6. MATERNAL HEALTH CARE

Maternal Health Care package of RCH programme focused more on ANC. The Maternal health care activities are implemented to strengthen and fulfill the RCH goals. ANC services provided by medical and paramedical professionals comprises of the regular physical checks with weight, height and blood pressure measure, Haemoglobin level test, consumption of IFA, Tetanus (TT) injection and the growth status and position of foetus. These primary services are made compulsory to be provided during the ANC check up from health facility. At least four checkups are made compulsory to complete the full ANC course in order to prevent and protect women from pregnancy related complication faced during the pregnancy and till the delivery. Janani Suraksha Yojna (JSY) is a scheme which is implemented in health facilities under the aegis of NRHM/NHM to promote institutional delivery and post-natal care to prevent maternal deaths.

6.1 Any ANC by Selected background Characteristics.

In Mizoram, 83.3 percent of the women had received at least one antenatal care (ANC) service during the pregnancy of their last birth in the three years period preceding the survey. The utilisation of Government health facility for ANC care (95.4%) is more than compare to private health facility (14.4) and community based services (2.4%) (Table 3.1).

Any ANC coverage by selected background characteristics are illustrated in Figure 7. Any ANC received among the non-literate are 32.2 percent as against 94.8 percent among the women educated for 10 or more years. There is significant rural-urban gap of 25.5 percentage point in availing any ANC, with 95.5 percent among urban residents and 70 percent among rural residents. Women who had received ANC with 1 living child is around 86.9 percent whereas woman with 4 and above living children is 80.6 percent.

The coverage of any ANC is highest in Serchhip district (99.7%), near universal coverage in Aizawl and Kolasib (95% to 99.7%) and lowest in Lawngtlai district (38.1%). Majority of women from Camphai, Mamit, Serchhip and Kolasib district are availed ANC care from government health facilities (99.4% to 98.5%) and 14.4 percent received it from private health facility. The proportion of women availing any ANC from private health facility utilization is highest in Aizawl district which is the highest in the state (Table 3.2).

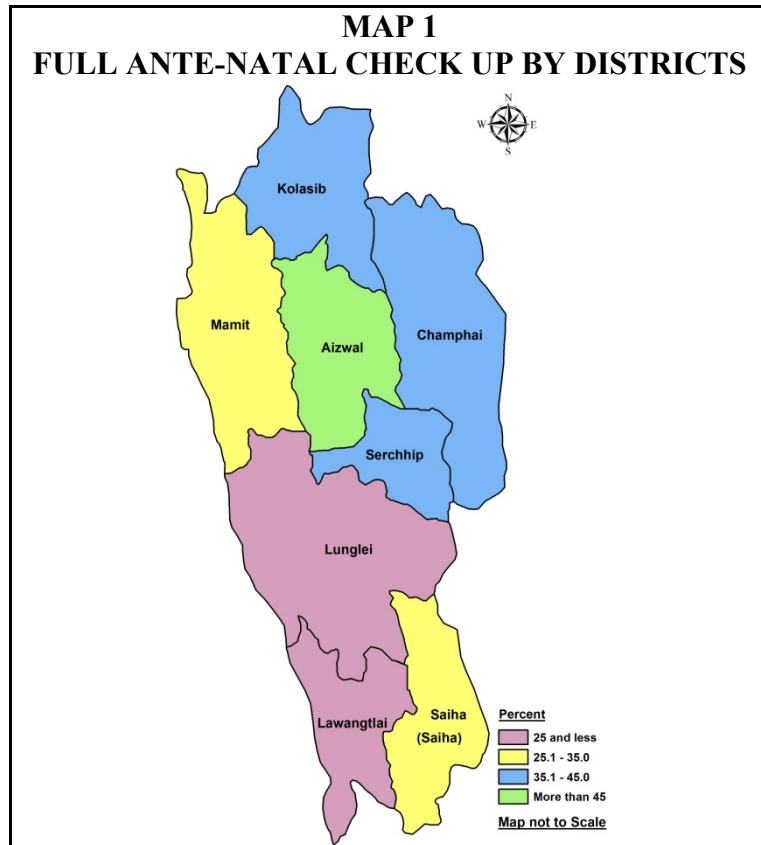

The lowest ANC coverage in government health facilities was in Lawngtlai District (81.5%). The DLHS-4 data reveals that more women availed from Government health facilities for ANC as compare to Private health facilities.

The specific components of ANC checkup which are supposed to be received by the women during the pregnancy were also collected. The proportion of women who received weight, height and blood pressure measurement, blood and urine tested, abdomen examined and sonography/ ultrasound test done are 74.2, 21.2, 73.3, 34.7, 35.3, 50.6 & 22 percent respectively, (Table No. 3.3). One important features of ANC check up in Mizoram in case of ultrasound test done is high among women who are having single children than 4+ living children (28.5% and 11.5% respectively), having 10 or more years of education (38%), rural-urban residence (8% and 34.9% respectively), and Hindu religion (29%). The women from Schedule caste are the highest (22.4%) as compare all others caste. The detail is shown in Table.3.3.

The proportion of women who had received at least three ANC (61.6%) and the women who had received first ANC in the first trimester of the pregnancy (54.3%) (Table 3.5 A). The women who had three ANC are highest among women who are having single living child (67.3%), having 10 or more years of education (76.3%), urban residence (77.2%), Christian religion (67.9%), Scheduled caste (64.4%) and there is no much difference by age group between 15-35 years. The women who had full ANC (i.e. at least 3 ANC visits with 100+ IFA tablets/ Syrups consumed at least 1 TT) in Mizoram is 36.7 percent. But

48.9 percent of women had 2 TT+ injections against 46.5 percent who had consumed 100+ IFA tablets/Syrups. The proportion of women who had received full ANC is highest in Aizawl district (53.8%) and lowest is 12.2 percent in Lawngtlai District (Table 3.6). District wise variation in coverage of full ANC is shown in the Map 1. The proportions of women who consumed 100 IFA tablets/syrup and received at least one TT injections are 46.5 percent and 80 percent respectively in Mizoram during DLHS-4 (Table 3.6).

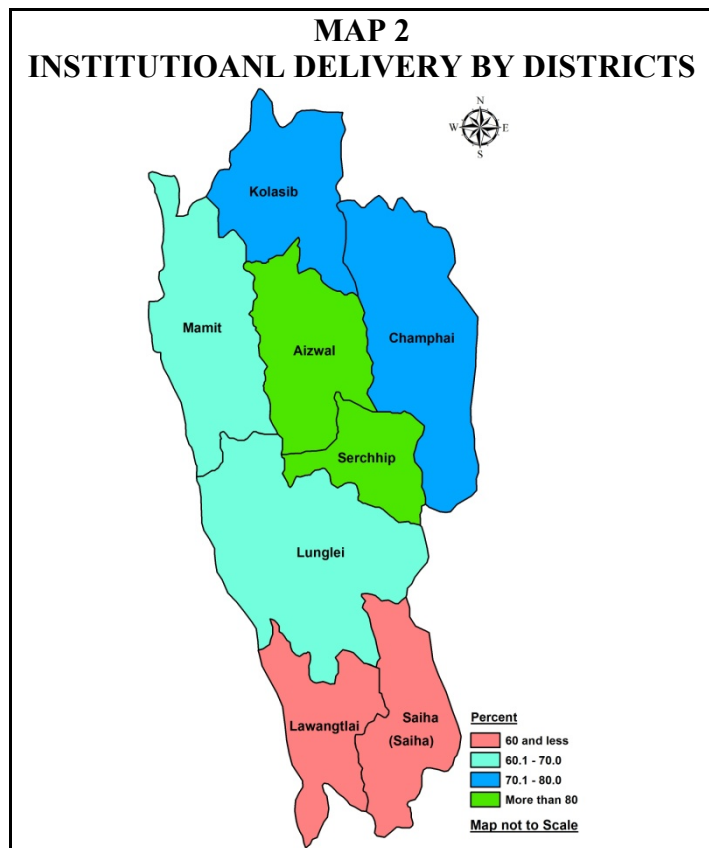

6.2 Institutional Delivery

In Mizoram, the institutional delivery has declined from 59 percent in DLHS-1 (1998-99) to 53 percent in DLHS-2 (2002-04), while it has increased from DLHS-2 to 56 percent in DLHS-3 (2007-08) to 72 percent in DLHS-4 (2012-13). The institutional delivery in Mizoram is presented in figure 7. More than seventy two percent of deliveries in the three years period preceding the survey which resulted either in still or live births were in both government and private health facilities (Table 3.7). The proportion of women having background of ten years or more education (91.8%) and having one living child (84.6%) are mostly going for institutional delivery. The percentage of institutional delivery ranges from 93.6 percent in Aizawl and 27.8 percent in Lawngtlai district. Around 79.5 percent of Skilled Birth Attendant (SAB) delivery shows that safe delivery is practiced in Mizoram). The home delivery cases (27.1%) who are assisted by

skilled persons are only 7.2 percent. The mean delivery cost in Mizoram ranges with a maximum of Rs.6,885 in Aizawl district to minimum is Rs.3,409 in Kolasib District (Table 3.9). In Mizoram, out of the 8 Districts, two districts are having the institutional delivery 80 percent & above in Aizawl and Serchhip districts and remaining 6 districts the percentage ranges from minimum 27 percent to 78 percent. District wise variations in institutional delivery is presented in the Map 2.

In Mizoram, only 0.2 percent of institutional delivery used ambulance and 53.1 percent jeep or car for transportation of delivery with an average cost of Rs.987. The used of jeep or car for transportation for institutional delivery was low among women with background of having 4 and above children (40.4%), Non literate (9.3%), Buddhist (8.2%) and others backward caste (17.7%) women. The mean delivery cost is Rs.3,958 in Government Health facilities and Rs.12,655 in private health facilities. There is a large variation of institutional delivery cost compare to government and private health facilities.

The JSY financial assistance for institutional delivery had benefitted to 60.9 percent delivery cases and 3.5 percent for home delivery cases (Table 3.8). The highest benefitted women for institutional are those in the age group of 15-19 (82.1%), urban residence (61.3%), having one living children (79.7%), Christian (61.8%) and Schedule Tribe (61.3%).

6.3 Complications during Pregnancy, Delivery and Post-delivery Period

The women who either do not take ANC or had an incomplete course of ANC are exposed to the risk of maternal death. In Mizoram, as much as 35.8 percent women who had still/live births in the three years preceding the survey had some complications during pregnancy (Table 3.6). Out of 8 districts, in 3 districts women faced high pregnancy complication percentage ranges from 48.4 percent in Serchhip district to 32.4 percent in Lunglei and remaining 5 districts faced complication ranges from 20.9 percent to 30 percent. The women who had faced pregnancy complication is highest in Serchhip district (48.4%) and lowest in Aizawl district (20.9%). Around forty nine percent who had complications during pregnancy sought treatment for the problem in Mizoram (Table 3.15).

Around 10.6 percent of women in Mizoram had faced at least one delivery complication. The main type of delivery complications experienced by women who had still or live births in the

three years period preceding the survey are mainly obstructed labour (11%), premature labour (17.6%), prolonged labour (50%), excessive bleeding (16.7%) and convulsion or high Blood pressure (25.2%). Delivery complication is higher among who undergone by Instrument or Assisted (29.4%) compared to Normal (9.2%) (Table 3.11). In all the districts of Mizoram, Serchhip district is highest proportion of women had a delivery complication (16.6%) and is lowest in Champhai (5.8%) (Table 3.15).

In Mizoram, 11 percent women had faced post-delivery complications. The major problem during post delivery period is high fever (23.7%), lower abdominal pain (52.8%) followed by and excessive bleeding 19.6 percent (Table 3.12). Among the women who had post-delivery complication, 56.9 percent had sought treatment (Table 3.15). In all the districts, women sought treatment for post delivery complication with highest in Aizawl district (81.8%) and lowest in Lawngtlai district (45.5%).

7. CHILD HEALTH AND IMMUNIZATION

To promote child survival and prevent infant mortality, NHM/NRHM envisages new born care, breastfeeding initiation, infant food supplementation at the right time, and a complete package of routine immunization for children. Twenty one percent of newborns were examined within 24 hours of birth (Table 4.1). Majority of women from Scheduled Tribes went for check-up in government health facilities (75.4%) than in the private health facilities (24.2%). In Mizoram, women who availed newborn care from government health facility constituted 75.4 percent as compared to 24.3 percent from private health facility. More newborns to women of urban resident (26.4%) and educated up to 10 or more years (23.9%) have received newborn care within 24 hours compared to others. There is enormous variation in rural areas in government health facilities (87.3%) and private health facilities (11.6%), in urban area also found variation in government (70.1%) and private (29.9%). Majority of women of Scheduled Tribes check-up in government health facilities (75.4%) than the private health facilities (24.2 %) (Table 4.1).

Majority (89.8%) of children under 3 years of age, born after January 1, 2008 were fed with colostrums and there is not much variation in this regard across selected background characteristics of women (Table 4.2). Highest proportion of children being fed with colostrums is 95.5 percent in Lunglei district and lowest is 71.7 percent in Lawngtlai district (Table 4.5).

In Mizoram about 82 percent of women had initiated breastfeeding within one hour of birth of the child. Among the women in Lawngtlai district is the least practiced of the initiation of breastfeeding within one hour of birth (54 %) and most widely practiced in Mamit (90.4%). However, 95.1 percent of women in Mizoram initiated breastfeeding within 24 hours of birth of their children, ranging from 90.2 percent in Lawngtlai to 98.1 percent in Aizawl (Table 4.5).

Duration of exclusive breast feeding practiced is high among infant under 2 to 5 months old is ranges from 73.3 percent to 60.3 percent. The introduction of food supplementation with semisolid and solid food started in 4-5 month along with breastfeeding. As the age increase percentage of the breast feeding declines and about 6.8 percent of children under 24 to 35 months breast fed along with other fluid, semi solid and solid food (Table 4.3).

7.1 Immunization Coverage of Children (aged 12-23 Months)

The immunization coverage of children (aged 12-23 months) has been recorded either from vaccination card or by asking the mother in case the card was not available. About 57.6 percent of children's immunization details was recorded from the vaccination card (Table 4.7). The full immunization coverage was 71.2 percent among children aged 12-23 months. The full immunization comprises of BCG, three doses of DPT & Polio and measles vaccines (Table 4.6). In Mizoram the coverage of BCG and measles are 88.4 percent and 79.7 percent respectively. Seven percent of children have not received any kind of immunization in the state.

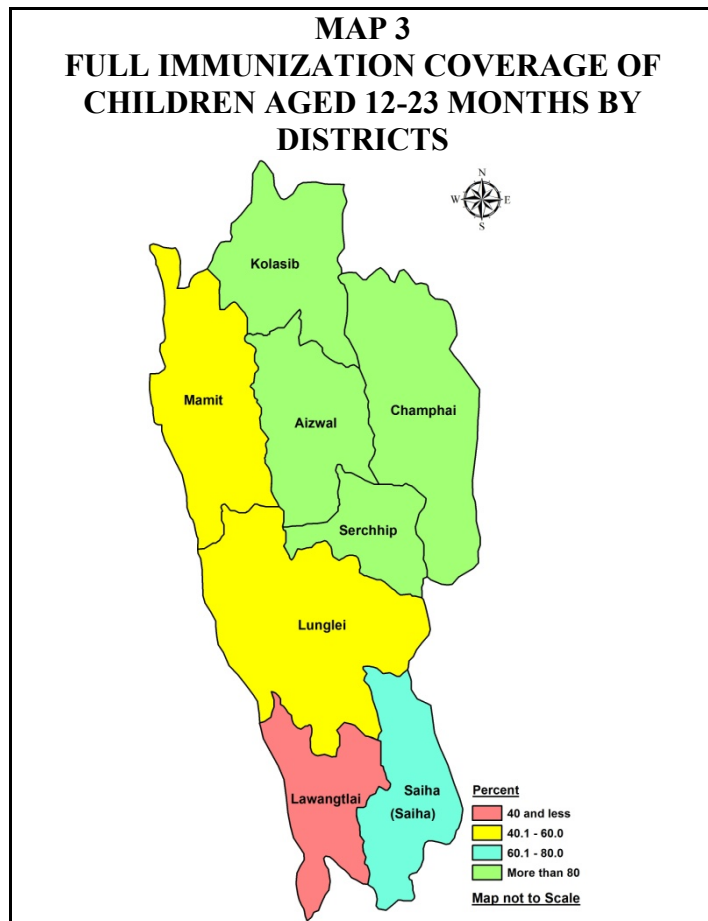

In the Districts of Mizoram, the highest full immunization coverage was in Aizawl with 86.8 percent and lowest in Lawngltai with 25.9 percent. Out of 8 Districts of Mizoram, 4 Districts covered full immunization less than 61 Percent whereas the remaining 4 Districts covered more than 80 percent (Table 4.7). While the coverage of BCG is high in all the districts except Lawngltai (40.6%). The coverage of DPT 3 ranges from 45.1 to 96.1 percent, Polio 3 ranges from 39.5 to 94 percent and coverage of measles fluctuates from 35 to 90.6 percent in the districts. Higher proportion of children of women educated 10 or more years (81%) and living in urban area (82%) received full immunization compared to their counterparts (Table 4.6).

The coverage of full immunization declined from DLHS-1 to DLHS-2 (around 68 to 33 %) but it has further increased by 21 percentage points from DLHS-2 to DLHS-3 (54%) and it further increased by 17 point from DLHS-3 to DLHS-4 (71%) as depicted in Figure 9. The coverage of full immunization of children is below 61 percent in Mamit, Lunlei, Lawngltai and Saiha while it is more than 80 percent in remaining districts (Table 4.7).

With regard to the location of vaccination of children, it was reported that Aganwadi Centre (0.9%), Sub-Health Centre (90.8 %), Primary Health Centre (1.2 %) and other government health facility (5.7%) (Table 4.8). District wise variations in coverage of full Immunization is depicted spatially in the Map 3.

Children who received at least one dose of Vitamin-A is 57.5 percent and received 3-5 doses is 42.2 percent in Mizoram (Table no. 4.9). In Serchhip district 75 percent of children aged 12-35 months received at least one dose of Vitamin-A, while in Lawngtlai district 20.6 percent children of the same age had received Vitamin-A. Kolasib, Aizwal, Champhai, Serchhip and Saihaare other districts of Mizoram where coverage of Vitamin-A is above the state level and remaining districts where coverage of Vitamin-A is below state level (Table 4.7). There is no much variation in background characteristics of the children who had received at least one dose of Vitamin-A in Mizoram. About 52 percent of children in Mizoram had received Hepatitis-B vaccination. Children of women educated 10 or more year (68.6%), living in urban area (64.6%) and having lower birth order (55.4%) more likely to receive Hepatitis B vaccination compared to their counterparts (Table 4.9).

7.2 Management of Diarrhoea and Acute Respiratory Infection (ARI)

The information on knowledge of diarrhoea and ARI management was collected from women respondents as part of assessment of child care knowledge. Majority (71.5%) of women has knowledge of diarrhoea management (Table 4.10) and 50.6 percent of women are aware of danger signs of ARI (Table 4.12).

The common practice followed by women for treatment of children who had diarrhoea was to give ORS (58.4%), salt and sugar solution (10.7%), plenty of fluids (13%), continue normal food (7.9%) and continue breastfeeding (8%) (Table 4.10). In Mizoram about 61 percent children who suffered from diarrhoea were treated by ORS, while 48 percent of them were given some treatment or the other (Table 4.11). Majority (72.8%) of children who had suffered from diarrhoea were treated in a government health facility and 27.6 percent in a private health facility (Table 4.11).

In Mizoram 50.6 percent of women were aware of danger signs of ARI. Among them 39.1 percent of women were aware of difficulty in breathing, 17.1 percent knew pain in chest and productive cough, 19.8 percent knew wheezing/whistling, 32.4 percent consider rapid breathing and 8.1 percent women having knowledge of others signs of ARI (Table 4.12).

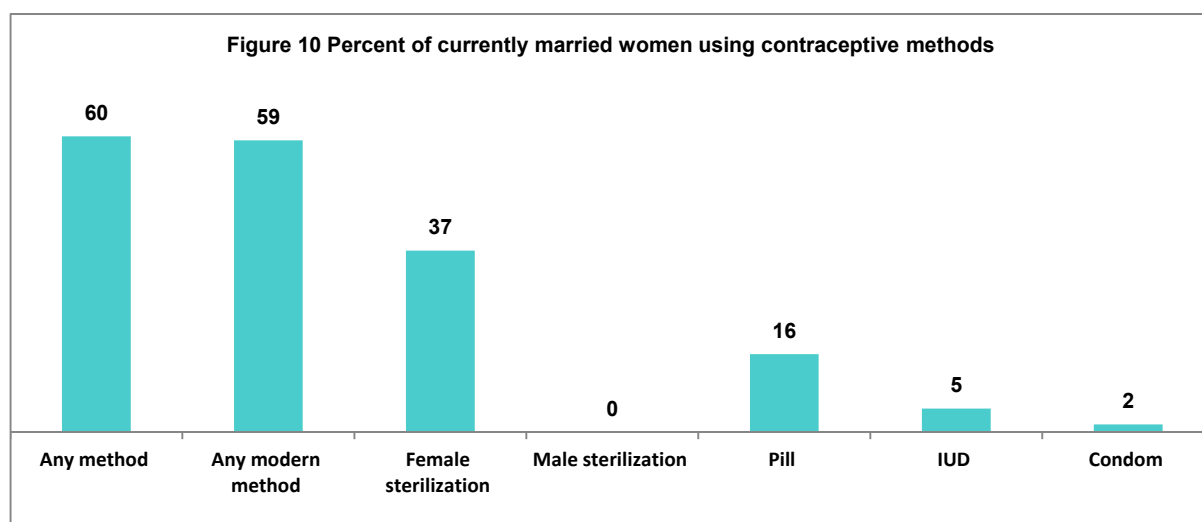

About 7 percent children had suffered from ARI in the last two weeks prior to the survey. Out of total children suffered from ARI, 66.8 percent children had sought advice/treatment, majority (58.4 %) of children had sought treatment at government health facility and about 38.4 percent sought at private health facility (Table 4.12).

The prevalence of ARI among children varied from 11 percent in Serchhip district to 2.8 percent in Champhai district. The treatment seeking for ARI or fever is 70 percent and above in the districts of Aizawl, Champhai, Serchhip and Lunglei (Table 4.13).

8. FAMILY PLANNING AND CONTRACEPTIVE USE

Family planning program in India has undergone sea changes in terms of strategies, focus and objectives. Post-ICPD the program orientation has evolved itself in human rights framework keeping in mind the central point to reduce unmet need for family planning. Strategies under NRHM were to create demand for family planning through enhancing child survival and improving maternal health.

There was awareness to the extent of 88 percent about female sterilization but male sterilization and Condom was known to only 22 and 61 percent of women surveyed respectively (Table No. 5.2). More than 68 percent of the women were aware of IUD and knowledge of Pill was 72 percent. The knowledge of traditional method was only 42 percent among women in Mizoram. However, new methods on menu of Indian program/or in market like female condom was known to only 9 percent among women. The female sterilization is the predominant limiting method being used by 37 percent of currently married women in 15-49 years and popular male oriented spacing or temporary method is Condom being used by 2 percent of husbands of currently married women. IUD and Oral pills are being ever used by 6 and 17 percent of women respectively (Table 5.4). Among the currently married women, the proportion ever using any modern method is 60 percent, while 62 percent of women ever used either modern or traditional methods. There is difference in rural-urban areas in the ever use of any modern contraception. However, female sterilization among rural women is 34 percent which is comparatively lower than the urban women (39%).

The status of current contraceptive use among currently married women or their husbands shows that 59 percent of them were using one or other modern methods, mostly female sterilization (37%). Use of Condom was only 2 percent among currently married women's husbands. The female sterilizations are more among urban women (39%) and women educated for at least 10 years (31%) compared to rural women (34%) and non-literates (24%).

Female sterilization, regardless of family size, was more among currently married women who have one or more living sons compared to those with no living son. Only 2 percent of women in 20-24 years, nearly 10 percent of women in 25-29 years and about 31 percent of women in 30-34 years have been found to have undergone female sterilization at the time of survey. The mean age at the time sterilization is 31 years. Among the currently married women, proportion continuing IUD use for less than 6, 2-3 and more than 3 years are 10, 26 and 14 percent respectively. Oral pill users continuing for more than 6 months constitute 66 percent of the total pill users and 41 percent of condom users are continuing for longer than 6 months.

Contraceptive prevalence rate (CPR) for any modern method was more than 60 percent in 3 districts out of 8 districts of Mizoram. Highest CPR for any modern method is 65 percent in Lunglei District and lowest is 47 percent in Lawangtlai district. About 94 percent of sterilization for limiting method has been done in government health facilities and 43 percent have availed government health facility for spacing methods. The high and low utilization rate of government health facility for limiting and spacing methods is true for all the districts of Mizoram. Nearly 45 percent of sterilized women and wives of sterilized men got monetary compensation for sterilization, with variation of 27 percent in Lunglei, 60 percent in Serchhip district. As many as in 53 percent of sterilization cases, monetary compensation is given at the time of discharge from the health facility.

Eleven percent of sterilized women, 36 and 4 percent among users of IUD and Pills, were informed about the side-effects before the adoption and 8, 5 and 14 percent of women using the aforesaid methods have experienced side-effect or health problems. Among the currently married women who have discontinued, the main reason cited is related to fertility (39%) while 37 percent mentioned side-effects and 24 percent mentioned other reasons. For the younger women in the age bracket between 20-29 years, reasons for discontinuation of contraception was primarily fertility related.

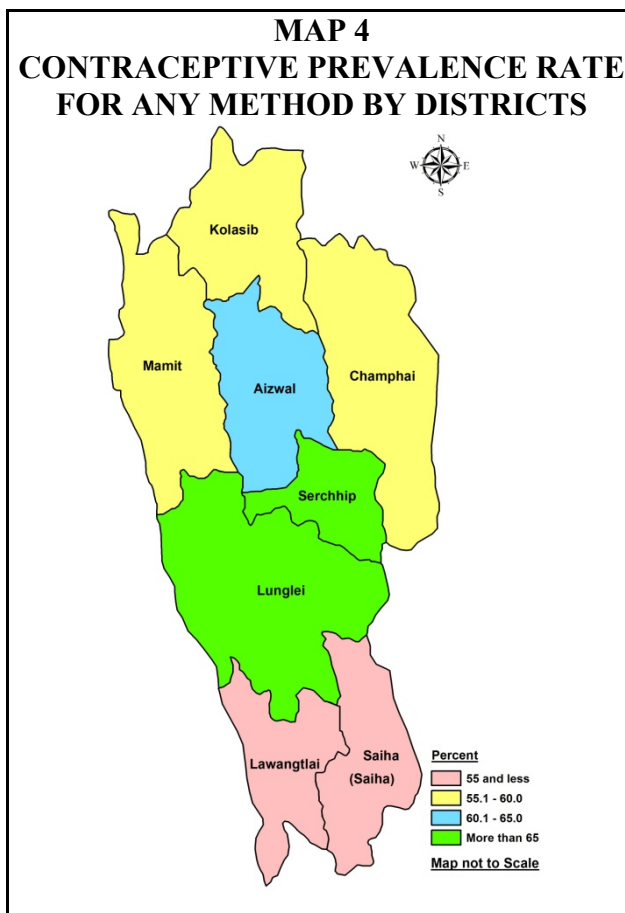

It was observed that around 3 percent of currently married women aged 15-49 years, were not using any contraception intend to adopt limiting method and 12 percent spacing method in future. Those who intend to adopt either limiting or spacing methods in future within 12 months, after 12 months and still undecided about the timing constitute 25, 14 and 61 percent respectively.

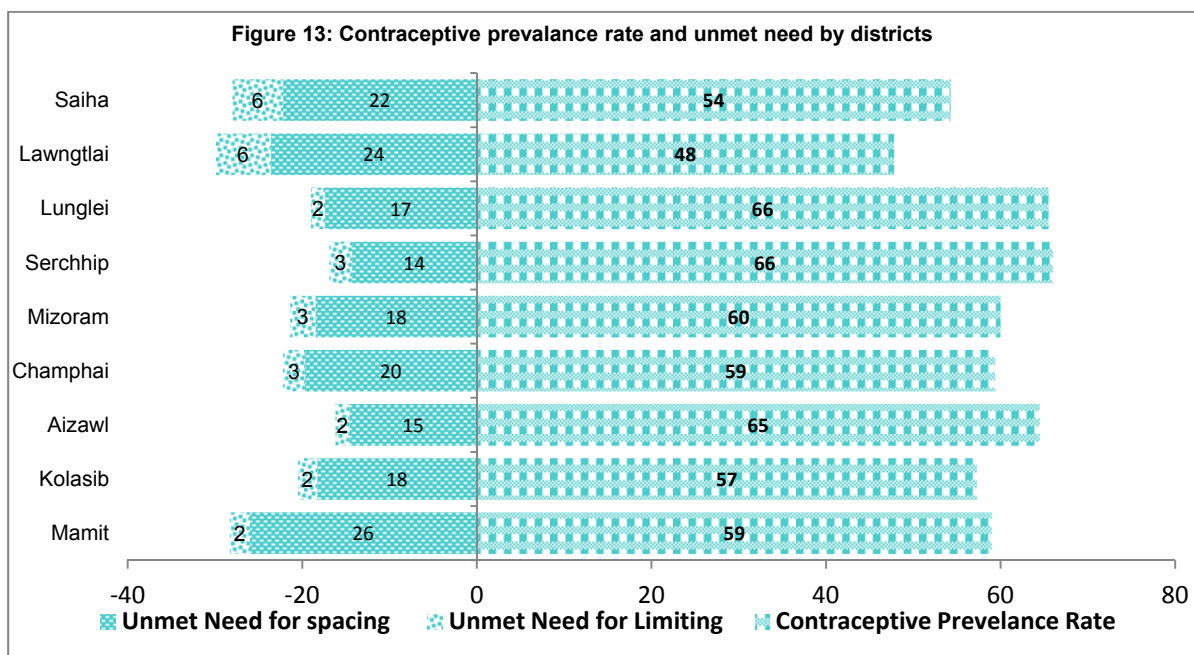

The unmet need for spacing included the proportion of currently married women who are neither in menopause nor had hysterectomy nor are currently pregnant and who want more children after two years or later and are currently not using any family planning method. The women who are not sure about whether and when to have next child were also included in unmet need for spacing. In Mizoram, 18 percent of currently married women have unmet need for spacing. Unmet need for

spacing is 34 percent for women with one living child and 35, 39, 28 percent for women aged 15-19, 20-24 and 25-29 years. On the other hand, currently married women who are still have physiologically potential for conceiving and want no more children are categorized as having unmet need for limiting. The unmet need of contraception for limiting is about 3 percent in the state.

Currently married women with unmet need for spacing is highest in Lawangtlai district (24%) and lowest in Serchhip (14%). On the other hand, unmet need for limiting is also highest in Lawangtlai district (6%) and lowest in Aizawl and Lunglei districts (2%).

The total unmet need of contraception has been substantially declined from DLHS-2 to DLHS-3. It was 25 percent in 2002-04, 14 percent in 2007-08. In 2012-13 it seems unmet need has increased to 21 percent. This is basically due to higher unmet need for spacing among the younger cohort, a sign of decline in the desire for large family size. District-wise contraceptive prevalence rate and unmet need are presented in figure 13.

9. REPRODUCTIVE HEALTH

Reproductive health addresses the issues of reproductive processes, encompassing functions and system at all stages of life. Reproductive health is the ability for the people to have a responsible, satisfying and safe sex life and have the capability to reproduce and the freedom to decide if when and how often to do so. This means that the right of men and women to be informed of and to have access to safe, effective, affordable and acceptable methods of fertility regulation of their choice, and the right of access to appropriate health care services that will enable women to go safely through pregnancy and childbirth and provide couples with the best chance of having a healthy infant. The burden of diseases among women is due to reproductive function and system. The five main causes of the disease burden among women in developing countries are maternal, Sexually transmitted disease, tuberculosis, HIV infection, Depressive disorders. DLHS-4 has obtained information on awareness and prevalence of RTI/STI, HIV/AIDS, information and ways to avoid AIDS.

9.1 Menstruation Related Problems

The women reported to have menstruation related problems and have specific symptoms during three months preceding the survey by background characteristics is given in table 6.1. Menstrual problems are experienced by 11 percent of women in Mizoram. The problems ranges from painful periods (48%) and irregular period (47%). The other problems reported are frequent or short periods (12%), prolonged bleeding (9%), absences of periods (4%), scanty bleeding. The differentials in menstruation related problems are found by age, place of residences and education of both husband and the wife. Women who had consummated their marriage below 18 years of age have had less menstruation related problems (10%) as compared to the women who had consummated their marriage above 18 years (12%). The related problems also increased with duration of marriage. More than 13 percent of women had reported to have menstrual problems whose marital duration was 10-14 years and more than 15 years.

9.2 Awareness of RTI/STI

The awareness of RTI/STI was obtained from ever married women. The women who ascertained about RTI/STI were further asked on the mode of transmission and symptoms of the disease. Table 6.2 shows the percentage of women who have heard of RTI/STI by background characteristics. Nearly one third of women in Mizoram had heard of RTI/STI. The proportion of women who were aware of RTI/STI was comparatively higher in urban areas (41%) than in rural areas (20%). Awareness of RTI/STI was lower among women with low age at consummation of marriage, non-literate women, and Buddhist women. Awareness of RTI/STI increases with education of women. Fifty five percent of women who had completed 10 or more years of schooling were aware about RTI/STI.

Television is important source of knowledge about RTI/STI, 80 percent women reported they had heard about RTI/STI from TV. Other major important sources of information about RTI/STI are from cinema (50%), print media (46%), Leaders/community meeting (41%), Health personnel (26%) and School/adult education programs (13%) The sources of knowledge about RTI/STI differ by education of women.

9.3 Knowledge Regarding Mode of Transmission of RTI/STI

Nearly 17, 19 and 18 percent of women reported unsafe delivery, unsafe abortion and unsafe IUD insertion respectively. Sixty five percent of women reported unsafe sex with persons who have many partners, unsafe sex with sex workers (63%) and unsafe sex with homosexuals(43%) as a mode of transmission of RTI/STI. The knowledge varies by residence, age at consummation, education of women and education of the husband.

Table 6.4 shows the common symptoms of reproductive tract infections/sexually transmitted infections among women. About 22 percent of ever married women have reported having symptoms of RTIs/STIs and 12 percent experienced abnormal vaginal discharge. The women reported itching or irritation over vulva (11%), pain in lower abdomen not related to menses (6%). About 63 percent of women discussed the RTI/STI related problems with their husband or partner (Table 6.5). The women mostly sought treatment for RTI/STI (63%) from Government health facility.

The women who have heard about RTI/STI varies from 15 percent in Lawangtlai district to 45 percent in Aizawl district. Women reporting any abnormal vaginal discharge varies 7 percent in Mamit district to 15 percent in Kolasib district. Out of 8 districts in Mizoram more than 30 percent of the women in 7 districts had sought treatment for any RTI/STI including abnormal discharge.

9.4 Awareness of HIV/AIDS

The awareness on HIV/AIDS was enquired from ever-married women between the ages 15-49 years. More than 85 percent of the women had heard about HIV/AIDs. The sources of knowledge on HIV/AIDS was Television (reported by 85 percent women) followed by cinema (55%), community leaders meetings (50%), print media (41%), health personal (24%), Husband (15%), school adult education programs (14%), radio and relatives/friends (8%) (Table 6.7). More than fifty seven percent of women reported shearing of

injection/needles and transfusion of infected blood as mode of transmission reported by 56 percent of the women. Fifty five percent of the women reported unsafe sex with sex worker and 52 percent of the women reported unsafe sex with person having many partners. Nearly 30 percent of women reported infected mother to child as mode of transmission of HIV/AIDS (Table 6.8). The reported modes of transmission of HIV/AIDS differ by residence, education of women and husband.

Table 6.9 shows knowledge of methods of preventing HIV. Sixty two percent women were of the view that HIV/AIDS can be prevented by avoiding risks of getting infected through blood. More than one fourth of women were of opinion that by using condom correctly during each sexual intercourse and more than 26 percent of women reported that having sex with one uninfected partner can prevent HIV/AIDS. The differences in the preventing HIV/AIDS were found by residence, age at consummation of marriage, education of women and husband. The misconception about transmission of HIV/AIDS from mosquito, flea or bedbug reported was reported by 24 percent of women. The other misconception were stepping on someone's urine/stool (7%), sharing food and sharing clothes (3%), hugging and shaking hand (2%) respectively.

The women who had heard about HIV/AIDS were asked the place to test the HIV/AIDS (Table 6.11). Nearly two third of the women knew the place where the HIV/AIDS could be tested. The differences in the place of test were found by residence, age at consummation of marriage, education of women and husband. Thirty five percent of women reported government hospital/dispensary and 12 percent reported private hospital/clinic as a place where people can go to test HIV/AIDS. The women who have heard about HIV/AIDS were asked if they had gone for the test. Fifty one percent of women had undergone for the test of HIV/AIDS. The women who had gone for the test. More than half of the women had undergone HIV/AIDS test (Table 6.12).

10. PERSONAL HABITS

Personal habits of adults (age 15 and above) such as consumption or abuse of tobacco and alcohol, and eating unhealthy foods are usually viewed from the lens of risk-taking behaviour due to their adverse health outcomes. The emerging morbidity pattern from the personal habits is a crucial predictor of current as well as future health status of a population. It has become increasingly important to understand and examine the impact, these habits have on overall health status in India in the context of the epidemiologic and demographic transitions. Besides, the treatment seeking behaviours for these illnesses reflects the availability, accessibility, as well as quality of health care services. Studies have shown evidences of correlation between the shift towards non-communicable diseases (NCD) and increasing risk-taking behaviours among adult individuals. For instance, excessive drinking is linked to acute and chronic physical health problems, particularly those related to the heart, blood circulation, respiratory, diabetes, mental health, cancer, crime and disorder, domestic violence, unprotected sex, unintended pregnancy, etc (Room, Baboor, and Rehm, (2005). Alcohol consumption contributes to many diseases and is now the fifth leading risk-factor for the global disease (Lim, Vos, Flaxman, et al, 2012). Also, the economic burden of these NCD is equally serious - i.e., a 10 percent rise in NCDs is found associated with 1 percent lower

rates of annual economic growth. However, programmes to combat NCDs were tremendously underfunded, and a low priority policy, as it is not part of the millennium development goals (MDG).

The WHO has recently stated that NCD such as cancer, diabetes, and hypertension are largest causes of death, and by 2020 cardiovascular diseases will be the largest cause of death and disability, including developing countries like India (WHO 2010). In 2012, the UN conference on sustainable development (Rio+20), referred to non-communicable diseases as “one of the major challenges for sustainable development in the 21st century”, emphasising the fundamental link between health and development. In the same year, the World Health Assembly endorsed an important new health goal: to reduce avoidable mortality from non-communicable diseases (NCDs) by 25% by 2025 (the 25 by 25 goal). The future threat to health is from NCDs, as the world also urbanizes faster than before.

Since 1990s India’s overall health status has shown tremendous improvement, which signals a change and shift in pattern of morbidity and causes of death to non-communicable diseases (NCD), despite still substantial contribution of communicable diseases. The NCD accounted for 42 percent of all deaths in India (56% in urban areas and 40% in rural areas), as compared to communicable diseases with 38 percent (RGI, 2003). Estimated prevalence of diabetes, hypertension, ischemic heart diseases (IHD) and stroke is 62.5, 159.5, 37.0 and 1.54 per 1000 respectively. In the National Health Policy (NHP), the Government of India (GOI) has committed to eradicating infectious illnesses and reducing the mortality associated with such illness (MOHFW, 2002). One of the goals of the NHP 2002 is a 50 percent reduction of deaths from TB, malaria, and other vector and water borne diseases by the year 2010.

This chapter presents findings on the personal risk-taking habits, acute and chronic (infectious and non-communicable) diseases, and their treatment-seeking behaviours.

10.1 Tobacco and Alcohol Use in India

Tobacco and alcohol use have been associated with a wide range of major diseases, including several types of cancers and heart and lung diseases. Studies have shown that in addition to sharing the same health risks as men, women who use tobacco or alcohol also experience difficulty in becoming pregnant, are at an increased risk of infertility, pregnancy complications, premature births, low-birth-weight infants, stillbirths, and infant deaths (USDHHS, 2004).

In India, information about tobacco and alcohol use among adults has been collected by various household surveys such as the National Sample Survey (NSSO) (50th round, 1998), NFHS (1992-93, 1998-99, and 2005-06), DLHS (2007-08), the Global Adult Tobacco Survey-India (GATS-India, 2009-10), etc., each survey with specific objectives and methodology. According to GATS India, 35 percent of adults in India age 15 and over use tobacco in some form or the other, with higher use among adults in most North eastern region (39-67%), east (36-50%), and central (40-53%) (IIPS & MoH&FW, 2010).

In India, there are varieties of tobacco products and its use is also very diverse. The most common ways of tobacco use are the smoking and oral (smokeless) variety. Dominant among the smoking form include cigarettes and bidis, while in case of the oral use of smokeless

tobacco, chewing or applying to the teeth or gums (scented/unscented, with paan) are the popular forms, which has also become very popular in most parts of the country. The DLHS-4 also collects information related to tobacco and alcohol usage directly from among the eligible adults (women age 15-49 and men age 15-54).

In case of alcohol consumption, household surveys in India show that alcohol use among adults, both men and women, is not uncommon, but the use is found much lesser than tobacco use. Alcohol consumption is higher among men than females. Study in India indicated the prevalence of current use of alcohol ranged from about 7 percent in Gujarat (state officially under prohibition) to a very high 75 percent in Arunachal Pradesh, and its consumption among women exceeded 5 percent only in the Northeastern region. DLHS-4 information on alcohol use by adult men and women comes from a substantial number of respondents (11,966 men and 12,491 women).

10.2 Tobacco Use in Mizoram

As shown in Table 7.1, overall a substantial proportion (82%) of adults in Mizoram use any kind of tobacco in one way or the other. However, tobacco use varies across the state by age, residence, education, region, etc. The survey clearly indicates that tobacco use is highest and more likely among men (84%), persons age 30 plus (around 90%), rural residents (85%), and among schedule tribe (82%), etc. Education does not seem to have an impact on the tobacco use in Mizoram. Among persons with 10 or more years of education 79 percent use some sort of tobacco.

In Mizoram, the adults are using more of the oral form (smokeless variety) of tobacco (78%) as compared to the smoking form (42%). Use of smoke tobacco is higher among men (63%) as compared with females (21%), in rural areas (47%) and also more likely to be higher among the adults age 25 and above (over 40%), and those with lesser education (around 47%), and also among the 'Other' caste (49%).

In general, it is observed that in Mizoram use of tobacco among adults increases with age, but in contrast, declines with increase in educational status. The pattern of using tobacco among adults also differs hugely and shows an interesting scenario across the districts in Mizoram. In all the 8 districts in the state, use of smokeless tobacco is over 70 percent (Table 7.4). Reporting of use of oral or smokeless form is highest in Mamit and Kolasib (83% each), followed by Saiha (81%). In case of smoking form of tobacco the use among adults ranges from 36 percent in Aizawl to 51 percent in Lawngtlai. Other districts in which at least 40 percent of adults are likely to smoke are Mamit, Kolasib, Champhai, Serchhip, Lunglei and Saiha.

The use of tobacco (all forms) among men is substantially high in Mizoram (79% for oral or smokeless and 63% for smoking). It is interesting to note that both forms of tobacco use is the lowest among teenagers (51% for smokeless and 30% for smoking), but increases sharply from age 20 onwards (among the youth) to older ages. Tobacco use is more common among men in rural areas (82% for smokeless and 69% for smoking) than urban males (77% for smokeless and 59% for smoking), although the urban-rural gap is not so wide. Among men also, education does not seem to have an impact on the tobacco use, as 78 percent of men

with 10 or more years of education use smokeless tobacco and 59 percent smoke (Table 7.2). Tobacco use among men by religious affiliation shows that highest tobacco use is among Buddhists (84% for smokeless & 72% for smoking). Both forms of tobacco use among men are observed to be highest among the 'Other' caste (82% for smokeless & 66% for smoking).

In Mizoram, strictly speaking, both forms of tobacco are used widely by men (79% for smokeless & 63% for smoking). However, in rural areas the proportion of non-smoke users (82%) is higher by about 5 percent than urban males (Table 7.2). About 25 percent of adult men use tobacco with paan, and below 1 percent with guthka/paan masala, while 53 percent use other forms of tobacco, which is higher by 5 percent in rural areas than urban areas (Table 7.5). In the case of smokers, more of rural men (69%) use this form, higher by about 10 percent, than those in urban areas (59%). About 43 percent of men are usual smokers (smoke at least once a day) in Mizoram. The proportion of usual smokers is 46 percent in rural areas as compared with 40 percent in urban areas (Table 7.6).

Generally, use of tobacco is found to be very less among women, more so when compared with men. However, in Mizoram, a substantial proportion of adult women (80%) reported using any kind of tobacco. Among the women tobacco users, while only about 21 percent smoke, a substantial proportion of them (77%) use the oral form or chew tobacco (Table 7.3).

The pattern of tobacco use observed among women is similar to that found among men. For instance, majority of women tobacco users prefer the non-smoke form. About 26 percent of women in rural areas smoke, compared with about 18 percent in urban areas. As presented in Table 7.3, among women, for ages 20 and above smokeless tobacco use is around 80 percent. Clearly, education does not play an important role in influencing such personal habits among women in Mizoram. Among those women who use non-smoke form/chew tobacco, about 34 percent used betel nut or paan, while 43 percent use other forms of tobacco (47% in rural areas & 39% in urban areas) (Table 7.5). Among women who smoke, about 10 percent are usual smokers (smoke at least once a day) (Table 7.6).

10.3 Use of Alcohol in Mizoram

Household surveys in India show that alcohol use among adults, both men and women, is not uncommon, but the use is found much lesser than tobacco use. Alcohol consumption is higher among men than women. Study in India indicated the prevalence of current use of alcohol ranged from about 7 percent in Gujarat (state officially under prohibition) to a very high 75 percent in Arunachal Pradesh, and its consumption among women exceeded 5 percent only in the Northeastern region. DLHS-4 information on alcohol use by adult men and women comes from a substantial number of respondents (11,966 men and 12,491 women).

As presented in Table 7.1, in Mizoram 17 percent of adults consume alcohol. In the state the level of consumption is found much higher among men (33% as compared with 2% among females), adults age above 25 (around 23%), and highest among 'Other' caste (24%). Like use of tobacco, education does not make much impact as an important factor. Use of alcohol is higher among more educated persons than non literates, but the proportions do not differ drastically. The level of alcohol consumption by religious affiliation shows that the least consumption is among Christians (1.6%) and highest among Buddhist (6.3%).

In Mizoram, alcohol consumption across the districts shows that of the 8 districts, only in 2 districts the level is around 20 percent (Table 7.4). The prevalence of alcohol use across the state ranges from 14 percent in Aizawl to about 24 percent in Lawngtlai. Consumption of alcohol is found high in districts such as Kolasib (20%), Mamit (18%), Lunglei (16%) and Serchhip and Saiha (around 15% each).

In Mizoram, consumption of alcohol is found more concentrated among males (33%), as compared with (2%) among females (Table 7.1). Men who are more likely to consume alcohol are those aged 20 and above (around 40%), non-literates (36%), who follow Buddhism religion (47%) and 'Other' caste (38%). The reporting of consumption of alcohol is seen among the teenagers (13%).

Only about 2 percent of adult females reported consuming alcohol in Mizoram (Table 7.3). The consumption of alcohol increases by age, with higher intake among older females age 20 and above (3%). Women who reported consumption of alcohol are those from rural areas (2%), non-literate (5%), and belonging to 'Other' caste (6%).

11. MORBIDITY STATUS

In DLHS-4, for the first time, information on morbidity status of the household members was collected from the household respondent. The main objective is to get a somewhat fair idea about the prevalence of both acute illnesses (suffered for a week) and chronic illnesses (for a month or more), including disability (current) and injury (in last one year), suffered by any household member prior to the survey. Respondents were asked about occurrences of such illnesses among the household members, and to name the illness, including those diagnosed. Further, in case of occurrence of any disability, injury or illness, respondents were also asked about the nature of care sought, the type and place of health facility where treatment was done.

Depending on the nature and duration, all the illnesses or diseases are classified as (a) acute, and (b) chronic. Acute illness refers to those that occur suddenly with severe symptoms for short period during the last 15 days prior to the survey. Example includes diarrhoea, dysentery, acute respiratory tract infection (ARI), jaundice with fever, fever with chill/rigors/malaria, fever with rash, reproductive tract infections (RTI), etc. In case of chronic illness, those symptoms that persist for longer than one month in the past one year prior to the survey. The list provided includes both symptoms and associated diseases categories.

11.1 Disability and Injury

From each of the selected household, DLHS-4 collected information from the head of the household or adult respondent on any injury and on five specific disabilities that household members may have suffered from such as mental, visual, hearing, speech, and locomotor. As it is difficult to capture the type of injury and its severity from lay reporting, assessment is made indirectly from the type and duration of hospitalization required for the injury.

As presented in Table 7.8, in Mizoram about 2 percent of the sample population reported suffering from any injury. The prevalence of any injury is marginally higher in the rural areas

(2.3%) compared to urban areas (2%). The prevalence of any injury (about 2% each) shows not much variation between males and females in the state.

About 3 percent of the injuries reported were treated in intensive care. However, 16 percent of injuries were treated as in-patient with stay for less than a week, and 12 percent reported they treated as in-patient with stay for more than 2 weeks. Interestingly, in Mizoram, about 62 percent of injuries were treated using other form of treatments, i.e. other than intensive care or staying/in-patient, such as out-patient, traditional healers, or home remedies. More males go for other treatments (65%) as compared with females, while women are more likely to be treated in intensive care or as in-patient with stay less than 1 week (17%). Higher percentage of rural residents go for other treatments (72%) than the urban residents (56%), while urban residents are more likely to be treated as in patient with stay more than 2 weeks (Table 7.10)

In Mizoram, among the five disabilities, the prevalence of hearing disability is a little higher (0.6%) as compared to other disabilities. Mental, visual and speech disabilities are the other disabilities reported in Mizoram (0.4%, 0.5% and 1% respectively). While reporting of mental disability is higher among females (0.4%) than males (0.3%), males reported higher hearing disability (0.6%) than females (0.5%). The prevalence of all disabilities is higher in rural areas (Table 7.9).

11.2 Reported Illnesses: Acute and Chronic

In order to assess the prevalence of illnesses from the selected household level in DLHS-4, the household respondents were first asked if any member of their households had suffered from any illness in the past one month or year. If reported that someone had suffered, more detail of the illness recorded, including main source of treatment. As mentioned earlier, all the illnesses are classified into (a) acute and (b) chronic, based on the nature and duration, and the information is collected from head or any adult member of the household.

Acute Illnesses

The prevalence of acute illness at the household level in Mizoram is 11 percent. There is no difference in the prevalence of acute illness by residence (11% in both rural and urban areas).

About 11 percent of household members reported suffering from any acute illness in Mizoram, and marginally more women (10.6%) than men (10.4%) reported to have suffered from any acute illness. Among the prevailing acute illnesses, fever (other than those with rash or jaundice) is reported by nearly 40 percent, followed by fever with rash (11%), Jaundice with fever (9%) diarrhea/dysentery (6%), and malaria (5%). Acute respiratory tract infection (ARTI) and Malaria are found to be higher in rural areas than in urban areas. The prevalence of other acute illness is found in high in urban area (31%) than rural areas (24%).

Nearly everyone who had suffered from any acute illness sought treatment. Among those who had sought treatment, 53 percent preferred treatment at 'Other' facility such as DOTS centre or at home. Around 32 percent were treated at government health facility, mainly in a hospital (17%), followed by a Primary Health Centre (PHC). About 10 percent of those who had acute illnesses got treated in a private facility, mainly in a hospital (5%), followed by a

dispensary/clinic (4%). In Mizoram, use of 'Other' health facility (such as DOTS centre or at home) for treatment of acute illness is quite common even in rural areas (60%), and more or less equally accessed by both males and females.

Chronic Illnesses

Survey results of chronic illnesses described pertain to prevalence, type, and source of treatment by sex and residence. In Mizoram about 4 percent of the households reported a member suffering from chronic illnesses that lasted for over a month in the past one year prior to the survey, which is found to be higher in urban areas (4%) than rural areas (Table 7.8). As shown in Table 7.13, reporting by symptoms of chronic illnesses suffered by household members is highest for diseases of the gastrointestinal system (11%), followed by diseases of respiratory system (9%), central nervous system (7%) and musculoskeletal system (5%). Interestingly, reporting of symptoms of chronic diseases other than the twelve identified diseases account for 54 percent.

In Mizoram, not much differences observed in the reporting of symptoms of chronic diseases between males and females, except in case of some diseases. For instance, more males reported symptoms related to respiratory system (11% as compared with 7% among females), gastrointestinal system (12% versus 10% among females), and central nervous system (8% as compared with 6% among females). In contrast, females reported more of symptoms related to disease of genitourinary system (4% compared to 2% among males) and for 'other' diseases (57% against 52% among males).

By and large, most chronic illnesses show more or less similar prevalence in both rural and urban areas. However, some of these chronic illnesses show slightly higher prevalence either in rural or urban areas. For instance, urban residents reported more of diseases of cardiovascular system (5%), central nervous system (8%) and gastrointestinal system (11%) than rural residents. In case of rural areas, much higher reporting related to skin diseases (3%) and 'other' diseases (57%) is observed.

Household respondents were also asked about the nature and source of treatment for chronic illnesses suffered by any of their household member. In Mizoram, 65 percent of those who suffered from chronic illnesses have details of diagnosis or treatment. About 16 percent have no details of diagnosis or treatment, and about 19 percent do not sought treatment at all. The proportion not seeking treatment (23%) is more in the rural areas as compared to urban areas (16%). Overall, 61 percent of rural residents and 68 percent of urban residents have details of diagnosis or treatment for the chronic illnesses. It is also observed that both males and females have more or less equal accessibility to health care services for chronic diseases (Table 7.13).

Interestingly, in Mizoram most people who suffered from chronic illnesses sought treatment at government facility (63%), even among rural residents (70%), and the proportion is 59 percent among urban residents. About 19 percent were treated at private facility (13% in rural areas and 23% in urban areas), while 17 percent reported being treated at home.

Persons who sought treatment for chronic illnesses were also asked about the details of the diagnoses at the facility. In Mizoram, diabetes (7%), hypertension (5%) and asthma or

chronic respiratory failure (6%) are the most commonly diagnosed chronic illnesses, followed by diseases related to heart and tuberculosis (around 3% each). Goitre accounts for about 1 percent of the diagnosed chronic illnesses. As expected, the proportion diagnosed with these chronic illnesses is much higher in urban areas, particularly hypertension and diabetes. The results show that more females suffered from hypertension (5% against 4% among males), while men are more suffered from tuberculosis (4% against 2%).

Contrast to situation in the general population, among the older persons age 60 and above the prevalence of most chronic illnesses is much higher. For instance, about 14 percent of older persons were diagnosed with diabetes, 7 percent with hypertension, and about 9 percent with asthma or chronic respiratory failure (Table 7.15). The prevalence of some of these chronic illnesses indicates that higher proportion of older persons in urban areas suffered from hypertension (9% as compared with 4% in rural areas) and diabetes (15% against 10% in rural areas). Among the older persons it is found that more females are diagnosed with diseases related to heart (5% as compared with 3% among males) and asthma or chronic respiratory failure (10% as compared with 9% among males). More of male older persons are diagnosed with diabetes (15%), TB (3%), cataract (1%) and stroke (2%).

11.3 Tuberculosis (TB)

Tuberculosis has re-emerged as a major public health problem in many parts of the world, often as a concomitant illness to HIV/AIDS. Tuberculosis, once known as the ‘White Plague’, is contagious and spreads through droplets that can travel through the air when a person with the infection coughs, talks, or sneezes. Today, TB is a leading cause of death among people who are HIV-positive. Worldwide, an estimated one-third of the nearly 40 million people living with HIV/AIDS are co-infected with TB. In most developing countries, TB would continue to be a serious health threat even in the absence of HIV/AIDS due to the public health challenges posed by poverty, high illiteracy, and poor sanitation. The GOI has stated that ‘In 2005, a total of 97 percent population was covered under the Revised National Tuberculosis Programme. The government allocated Rs. 680 crores for the National Tuberculosis Control Programme (NTCP) in the 10th Plan (DGHS and WHO, 2005). In Mizoram, about 3 percent of the household population diagnosed with TB, which is found higher among males and in rural areas.

12. NUTRITION AND HEALTH

The DLHS-4 collected data on the nutritional status of children by measuring the height and weight of all children under age five in the selected households. The nutritional status assessment helps to identify sub groups of child population that face increase risk of faltered growth and potential health risks and vulnerabilities. The nutritional status of children in the survey population is compared with WHO child growth standards, which are based on an international sample of ethnically, culturally and genetically diverse healthy children living under optimum condition that are conducive to achieving a Child’s full genetic growth

potential(WHO, 2006)¹. These standards can therefore be used to assess nutritional status of children all over the world, regardless of ethnicity, social and economic influence and child feeding practices. Accordingly, three standard indices of physical growth that describes the nutritional status of children are height-for-age (stunting), weight-for height (wasting) and weight -for-age (underweight). Each of these indices provides different information about growth and body composition that can be used to assess nutritional status.

In DLHS-4, all children listed in the household, who were born in year 2008 or later were eligible for measurement of their height and weight. Thus, height and weight measurements were collected even from those children whose mothers may not have been interviewed in the survey. For this purpose, all the survey team carried with them two scales and two height boards, which were standardized in all aspects and calibrated for accuracy. Recumbent length was recorded for children under age two years. Standing height was measured for all other children. Table 8.1 represents percentage of children below age five classified as malnourished according to three anthropometric indices of nutritional status (height for age, weight for height and weight for age) by some selected background characteristics. The analysis is based on information collected from 4131 children from Mizoram for whom complete and erodible anthropometric and age data are available.

12.1 Height-for-Age (Stunting)

Height-for age measures linear growth. A child who is more than two standard deviations below the median (-2SD) of the WHO reference population in terms of height-for-age is considered short for his or her age are stunted. This condition reflects the cumulative effect of chronic malnutrition.

In Mizoram, 38 percent children under age five are stunted and 15 percent are severely stunted. Variation in the prevalence of stunting by age group shows that stunting is highest (46%) in children age 25-35 months, followed by those in age 19-24 months (44%) and the lowest (18%) in children below age 7-12 months. Prevalence of sever stunting shows a similar pattern, with the height proportion of sever stunting in children age 19-24 months (28%), followed by among those age 25-35 months (21%).

Sex differential in the prevalence of stunting is pronounced as male children (40%) are more likely to stunt than female children (36 %). The sex differential also pronounced even in ease of severe stunting. Children under age five living in rural areas and coming from other backward classes as more likely to be stunted than others.

The prevalence of stunting is not uniform across different districts in Mizoram. Stunting is the highest in Champhai and Saiha (43%) followed Mamit (41%). While, the prevalence of stunting is the lowest in Serchhip (29 %) followed by Aizwal (30 %). Severe stunting is the lowest in Serchhip (10%), and Aizwal (11%). On the other hand, Saiha portrays the highest prevalence even in case of sever stunting (21 %).

¹ World Health Organizations (WHO) Multicentre Growth References Study Group. 2006. *WHO Child Growth Standards: Length/Height-for-Age, Weight-for Length, Weight-for-Height and Body Mass Index for- Age: Methods and Development*. Geneva, Switzerland: WHO.

12.2 Weight -for-Height (Wasting)

Weight-for-height describes the current nutritional status. A child who is more than two standard deviations below (-2SD) the reference median for weight-for-height is considered to be too thin for his or her height, or wasted. This condition reflects acute or recent nutritional deficit. As with stunting, wasting is considered severe if the child is more than three standard deviations below the reference median. Overall 18 percent children in Mizoram are wasted and 7 percent are severely wasted. Analysis by age group shows that wasting ranges from a maximum 28 percent in children age 0-6 months to the minimum 15 percentage in children age 25-35 months. Children residing in rural areas are more likely to be wasted (20%) than children living in urban areas (16%). Children from other backward classes are more likely to be wasted (26%) than the children in other caste groups. Variations by district portray that wasting in children ranges from 16 percent in each of Aizawl and Champhai to 22 percent in Lawngtlai.

12.3 Weight- for-Age (Underweight)

Weight-for-age is a composite index of weight-for height and height-for-age. Thus, it does not distinguish between acute malnutrition (wasting) and chronic malnutrition (stunting). A child can be underweight for his age because he or she is stunted, because he or she is wasted, or both. Table 8.1 reveals that 27 percent of children under age 5 are underweight and 7 percent are severely underweight. The proportion of underweight children is the highest (32%) among children age 25-35 months and the lowest (20 %) among children age 0-months. The sex differential in the proportion of underweight children is not so much pronounced. Rural children are more likely to be underweight (31%) than the urban children (20%). Children from scheduled tribes and other backward classes are relatively less likely to be underweight than their counterparts. By districts, underweight in children ranges from 22 percent in Aizawl to 34 percent in Lawngtlai.

12.4 Body Mass Index of Women

In many countries, chronic energy deficiency characterized by BMI of less than 18.5 among adults remains the predominant problem, leading to low productivity and reduced resistance to illness. Prevalence of overweight among women is also growing problem in developing countries. Overweight individuals are predisposed to a wide range of health problems including diabetes and heart diseases and also poor birth outcomes for pregnant women. The BMI is used to measure thinness or obesity. It is defined as weight in kilograms divided by height in meters squared (Kg/m^2). A BMI of less than 18.5 is used to define thinness or acute under nutrition. A BMI of 25 or above usually indicates overweight and a BMI of 30 or above indicates obesity.

In DLHS -4, height and weight measurements in Mizoram were obtained for 6813 women age 15-49 who were present in the sample households at the time of survey. Table 8.3 presents percentage of women age 15-49 by their BMI. The mean BMI is 22.2, which falls in the normal BMI classification. About seven-tenths (69%) of women age 15-49 have a normal BMI, 16 percent are undernourished or thin (BMI less than 18.5) and 15 percent are overweight or obese (BMI 25 or higher). It is evident from the table that there is profound

variation in BMI by some selected background characteristics of women. Women age 15-19 are more likely to be thin or undernourished (24%) than women in other age cohorts. Rural women are more likely to be thin or undernourished (19%) than their urban counterpart (14%), where as urban women are almost 1.4 times more likely to be overweight or obese as compared to rural women (18 and 10% respectively). Educational attainment show an consistent relationship with the proportion of thin or undernourished women. Among women who are non literate, nearly one fifth of them are thin or underweight and 7 percent are overweight or obese. The percentage of overweight or obese is maximum among women having more than 10 years of schooling. Women from scheduled caste households, having larger potential to have food insecurity, are much more likely to be thin in comparison to those from households from other caste-groups. Proportion of women who are thin or underweight is not uniform across districts of Mizoram. It ranges from the minimum of 10 percent in Aizawl to 24 percent in Lawngtlai. On the other hand, proportion of ever married women who are overweight or obese is the highest in Aizawl (20%) and lowest in Lawngtlai (9%)

12.5 Prevalence of Anaemia

Anaemia , characterized by a low level of hemoglobin in the blood, is major health problem in developing countries, especially among young children and pregnant women. Anaemia among pregnant women may be an underlying cause of maternal mortality, spontaneous abortion, premature births, and low birth weight. The most common cause of anaemia is inadequate dietary intake of nutrients necessary for synthesis of hemoglobin, such as iron, folic acid, and vitamin b12. Anaemia also results from sickle cell disease, malaria, and parasitic infections (Benoist et al. 2008)². It is against this background, a number of interventions have been put in place to address anaemia in children in developing countries. These include expanded distribution of iron supplements and deworming medication to children age 1-5 every six months.

In DLHS-4, all the usual residents of the selected households including children age 6-59 months were included in the anaemia testing, where blood drops were collected using dried blood spot (DBS) method and tested in designated laboratories. The process of blood collection consists of obtaining blood droplets by pricking in the middle or ring finger with a retractable and non-reusable lancet. Before pricking, the finger was cleaned with a swab containing 70 percent isopropyl alcohol and allowed to dry. In case of those children where blood droplets were not possible from middle or ring finger, heel pricking was practiced and DBS were prepared.

Table 8.5 shows the anaemia status of children age 6-59 months by some selected background characteristics. Over seventh-tenth (71 %) of children age 6-59 months suffer from some level of anaemia (Hb <11.0g/dl), 12 percent of children have mild anaemia and 45 percent have moderate anaemia (Hb 7.0-9.9g/dl). About 13 percent of children age 6-59 months have severe anaemia (Hb <7.0 g/dl). There is slightly different has been found in prevalence of anaemia among children age 6-59 months by sex of child and place of

² Benoist, B.D., E. McLean, I., and M.Cogswell (eds.). 2008. *Worldwide Prevalence of Anaemia 1993-2005: WHO Global Database on Anaemia*. Geneva, Switzerland: World Health Organization

residence. The prevalence any anaemia varies significantly by caste of the household to which children belong to. Of course, Buddhist's children are comparatively less likely to suffer from any anaemia than those from other religion.

The prevalence of any anaemia declines sharply among school going population age 6-19 years (56%). The proportions of school going population age 6-19 years who suffer from mild and moderate anaemia are 15 and 40 percent respectively. The pattern in decline in any anaemia with increasing age is linear in nature with the maximum (70 %) among those in the age-group 6 to 10 years and minimum (58 %) in those age 17-19 years. Female children and those living in rural areas are little more likely to be anemic (Table 8.6). The prevalence in anaemia also declining linearly with increasing years of schooling, from 73 percent among non literate to 55 percent among those having 10 or more years of schooling. Scheduled caste and scheduled tribes are more likely to be anemic even in the school going population age 6-19 years.

Prevalence of anaemia declines further in case of adult population age 20 years and above. It is evident from Table 8.7 that over six-tenths (56%) of adult age 20 years and above are anemic in Mizoram. Adult women are 1.3 times more likely to be anemic than their male counterparts. Similar to the school age population (age 6-19year) adult's population portrays a decreasing prevalence of anaemia with increasing age groups. The pattern in decreasing in prevalence of anaemia remains the same for women but not for men. There is little bit differential to be anemic by palace of residence (Table 8.7). Increasing years of schooling shows linear decline in the prevalence of anaemia across the different years of schooling. Buddhist religion portrays a distinct pattern with relatively higher prevalence of anaemia even among adult age 20 years and above, which may have definite implication for the food security scheme in the state.

Prevalence of anaemia among pregnant women poses much sever health consequences and may be an underlying course of maternal mortality, spontaneous abortion, premature births and low birth weight, Table 8.9 presents the percent of pregnant of women age 15-49 classified as having iron-deficiency (anaemia) by degree of anaemia and some selected background characteristics. It is evident from the table that almost four-fifths (60%) of pregnant women in Mizoram are anemic. About 18 percent of them have mild anaemia (10.0-10.9 g/dl), 37 percent have moderate anaemia and 8 percent have severe anaemia. Pregnant women in Mizoram who are younger in age (specifically age 15-29); those living in rural areas and coming from scheduled tribes households are more likely to be suffering with anaemia.

12.6 Prevalence of Diabetes

Diabetes has serious consequences for individuals and poses a large burden on health services, especially in developing countries. According to the International Diabetes Federation (IDF), diabetes poses a daunting challenge to the sustainable development of the nation, as almost every tenth adult in India is estimated to be affected by either diabetes or pre-diabetes (IDF 2013)³. The latest global figures on diabetes, released by the International

³ International Diabetes Federation (IDF).2011.Diabetes Atlas, 5th edition Brussels, Belgium: IDF

Diabetes Federation (IDF), has raised a serious alarm for India by saying that nearly 52% of Indians aren't aware that they are suffering from high blood sugar (IDF, 2013). In DLHS-4, women and men age 18 and older in the selected households were eligible to have their blood glucose level tested. The blood glucose was measured using portable glucometer namely SD code free, where blood droplets were obtained by pricking in the middle or ring finger with a retractable and non-reusable lancet. Before pricking, the finger was cleaned with a swab containing 70 percent isopropyl alcohol and allowed to dry. In the process, the first two drops of blood were wiped away and third drop was drawn into the glucose strips.

Table 8.10 and 8.12 present data on random blood glucose values for men and women age 18 and above from the sample households included in DLHS-4. Data shows that 4 percent of men and women age 18 and above in Mizoram suffer from diabetics as the level of blood glucose among those have been 160mg/dL or higher. Another 5 percent of men and 4 percent of women age 18 and above in Mizoram are pre-diabetic. However, over ninety percent of men as well as women have normal level or even lower level of blood glucose.

Prevalence of diabetes increases linearly with increasing age among men as well as among women age 18 years and above. Men age 60 & above are over 10 times more likely to suffer with diabetes as compared to those in the age-group 18-29 years. The pattern remains by and large same even among women age 18 years and above - 1.2 percent in the age group 18-29 years and 12.2 percent in age 60 years & above (Table 8.12). Men and women age 18 and above who reside in urban areas are more likely to suffer from diabetes than their rural counterparts (1.5 times and 1.2 times respectively). Men and women who are illiterate and having less than 5 year of schooling are more likely to suffer from diabetes than their counterpart. Level of diabetes prevalence cuts across religion group, which may have implication for the differences in life style and food habits. Adult men and women in Muslim religion are very less likely to suffer from diabetes than the other religion's category. Though cast differentials in prevalence of diabetes in also profound but men and women who are non SC/ST and non OBC are more likely to suffer from diabetes than others, which may be primarily due to changes in their life styles and dietary practices. Tables 8.11 and 8.13 present variation in the prevalence of diabetes among adult men and women age 18 and above across different districts of Mizoram. Among districts, men in Serchhip have the highest prevalence of diabetes (7%) followed by Kolasib (6%) and Aizawl (5%). On the other hand, men in Mamit and Saiha (2% each) have relatively lower prevalence of diabetes among different districts of Mizoram. The pattern remains by and large the same even if we analyze the prevalence of diabetes among adult women in different districts of Mizoram. The prevalence is the highest among adult women in Serchhip (8%) and lowest in Mamit and Saiha (2% each).

12.7 Prevalence of Hypertension

Blood pressure rises and falls throughout the day. When blood pressure stays elevated over time. It is called high blood pressure. The medical term for high blood pressure is hypertension. Raised or high blood pressure acts as one of the contributing and intermediate risk factors for developing coronary heart disease, stroke, and kidney disease. The measurements taken for blood pressure in DLHS-4 were not intended to provide a medical

diagnosis of the disease but rather to provide a cross-sectional assessment of the prevalence of high blood pressure in the population at the time of the survey. Although the results of the blood pressure measurements are regarded only as a statistical description of the survey population, they provide insight into the size and characteristics of the population at risk for hypertension. The DLHS-4 is used Ross Max AW150 blood pressure monitor model; the automatic device included separate cuffs for measuring blood pressure in respondents with small, medium and large arm circumferences. Interviewers were adequately trained to use this device according to the recommended protocol. Two health investigators were included in each team for data collection.

Two measurements of both systolic and diastolic blood pressure were taken during the survey at approximately ten minutes interval and the average measurement was used to report respondent's blood pressure values. Tables 8.14 and 8.16 present the information on blood pressure values for men and women age 18 years and above by some selected background characteristics. In the table the blood pressure level has been defined into six categories depending upon various combinations of systolic blood pressure (SBP) and diastolic blood pressure (DBP). The value of SBP greater than 140 mmHg or DBP greater than 90 mmHg is defined as hypertensive with elevated blood pressure, which may have implications for need for medication on a priority basis(AHA, 2003)⁴. In DLHS we have taken SBP 130-139 or DBP 85-89 as the pre-hypertension. It is evident from Tables 8.14 and 8.16 that 16 percent of men and 9 percent of women age 18 years and above in Mizoram are in the stage of pre-hypertension, while 24 percent men and 14 percent of women age 18 years and above are in the stage of hypertension and require medical attention on a priority basis. A relatively larger proportion of men age 18 years and above living in urban areas are found to be hypertensive (26%) than those living in rural areas (21%). On the other hand prevalence of hypertension is same for women living in rural area as well as urban area (14%). The pattern is by and large the same even in case of the pre-hypertension though the magnitude of difference reduces considerably.

The pattern in prevalence of pre-hypertension and hypertension across different districts of Mizoram are not uniform. Among men age 18 years and above, prevalence of pre-hypertension ranges from a minimum in Serchhip and Lawngtlai (13% each) to the maximum in Champhai (18%). In case of hypertension, the prevalence ranges from a minimum in Lawngtlai (21%) to the maximum in Kolasib (27%).

In case of women age 18 years and above, the prevalence of pre-hypertension is the lowest in Mamit, Kolasib and Aizawl (8%) among the 8 districts of Mizoram. On the other hand, Champhai and Lunglei (11 percent some of the leading districts having higher prevalence of pre-hypertension among women age 18 years and above. District wise variation in the proportion of women age 18 years and above suffering with hypertension (SBP \geq 140 or DBP \geq 90) also portrays the same pattern with the lowest proportion of women in Saiha (10 %) and the highest proportion in Champhai (17%), Kolasib (16%) and Aizawl (15%).

⁴ American Heart Associations. <http://www.heart.org/HeartORG/>

12.8 Use of Iodized Salt

Salt used in the household is the most common vehicle for iodine fortification to prevent the public health concerns of iodine deficiency disorders. The compound used for fortification of salt is potassium iodate (KIO₃). According to the World Health Organization, a country's salt iodization program is considered to be on a good track to eliminate iodine deficiency when 90 percent of households use iodized salt. The 2012-13 DLHS-4 made an effort to assess household iodized salt consumption by testing iodine contents in the salt being used by the household. Table 8.18 shows the proportion of households using iodized salt according to some selected background characteristics. Over all, salt was tested for iodine contain in 99 percent of household in Mizoram and 72 percent households were found to use salt with adequate iodine contain. Another 25 percent households were found to use salt with iodine but the proportion of iodine contain was not adequate. There is difference in use of iodine salt by place of residence (Table 8.18). Analyzing the variation in proportion of household using iodized salt by districts; it is evident from Table 8.19 that it ranges from a maximum in Saiha (76%) to the minimum in Lawngtlai (62%).

13. HEALTH FACILITIES

The basic objective of the population linked facility survey conducted for the first time in DLHS-3 is to collect data on health personnel, availability of drugs/medicines, equipments, basic RCH care amenities, communication means and infrastructure at the level of, PHC and CHC, in order to assess the adequacy of RCH services in rural areas.

In DLHS-4 facility survey all Community Health Centres (CHCs) and the District Hospitals (DH) were covered. All Sub-Health Centres and Primary Health Centres (PHCs) which were expected to serve the sampled population of selected PSU were also covered.

In Mizoram, the average sampled rural population served per Sub-Health Centre, PHC and CHC are 3,311, 6,783 and 12,223 respectively (Table 9.1). In total, villages were surveyed in DLHS-4 and the RCH services of these sampled villages were catered by 140 Sub-Centres, 42 PHCs and 11 CHCs.

Out of the 140 Sub-Health Centres functioning in government building, 62.8 percent have regular electricity (Table 9.2). In 39.1 percent of these Sub-Health Centres there are labor rooms; and out of this, 82.4 percent of the labor rooms are currently in use. Toilet facility is available in 87.7 percent of the sampled Sub-Centre located in government buildings. And, 87.0 percent of these Sub-Health Centres running in government buildings have provision for water.

Citizen's charter is displayed in 67.1 percent of the sampled 140 Sub-Health Centres (Table 9.3). The proportion of sampled Sub-Health Centre facilitated by Village Health & Sanitation Committee (VHSC) and those that received untied funds is 96.4 percent and 95.0 percent respectively.

Eighty nine percent of SHCs are having Auxiliary Nurse Mid Wife (ANM). Additional ANM available in SHCs (18%), and 64.3 percent SHCs are having Male Health Worker (MHW) available.

In Mizoram, out of 42 sampled PHCs, 93 percent of the PHCs have MOs. At the PHC level, all the districts, except Lawngtlai and Saiha districts all the surveyed PHCs are having Medical Officers (MOs). Availability of other human resources like LMOs, and Pharmacists are available in 12 percent, and 71.4 percent PHCs respectively (Table 9.5).

Residential quarters available for MOs in 95.2 percent of the sampled PHCs. 90.2 percent PHCs are functioning on a 24 hour basis. At least four beds are available in 95.2 percent of the sampled PHCs. Availability of regular power supply is found in 64.3 percent of the PHCs. Out of 42 PHCs more than two third of the PHCs are having functional vehicles /on road (Table 9.6).

Newborn care services are available in 92.3 percent of the sampled PHCs, 16.2 percent provide referral services for delivery cases during last one month, and 9.5 percent PHCs have conducted at least 10 deliveries during last one month prior to the survey (Table 9.7).

Ninety five percent of the PHCs have received untied fund for previous financial year and it was utilized by 100 percent of the PHCs. Rogi Kalyan Samiti (RKS) has been constituted in 95.2 percent of the sampled 42 PHCs and the Citizen's Charter displayed found in 85.7 percent of sampled PHCs (Table 9.8).

Out of total 11 CHCs which have Obstetric/Gynecologist (2 CHCs) Pediatrician (1CHC), Anesthetist (3CHCs) where as non of the CHC have Public Health Manager in Mizoram.

Six CHCs are designated as First Referral Units (FRUs) form the 11 CHCs in Mizoram. All 11 CHCs have functional Operation Theatres (OTs) and provided newborn care services.

All 11 CHCs have utilized untied fund for previous financial year. Displayed citizen's charter is found in 10 CHCs, RKS constituted by all 11 CHCs and all CHCs have monitored RKS activities regularly (Table 9.11).

Two Sub-Divisional has been surveyed in Mizoram at the time of the survey. Total 8 District Hospitals have surveyed in Mizoram. Pediatricians has been found in 4 DHs, Radiographers (1DH) The facility of 2D Echo (2 DHs), Ultra Sound facility is available in all the DHs. Critical care area is available in (03 DHs). Suggestion and Complaint boxes are available in 7 DHs out of total 8 District Hospitals in Mizoram.

BACKGROUND CHARACTERISTICS

TABLE 1.1 BASIC DEMOGRAPHIC INDICATORS

Basic demographic indicators of Mizoram and its districts, Census 2011, India

State/Districts	Population (in thousands)	Percentage urban	Percentage decadal growth rate ¹	Sex ratio ²	Percentage literate 7+		
					Male	Female	Total
Mamit	86.4	17.3	+37.56	924	89.1	80.4	84.9
Kolasib	84.0	56.2	+27.28	956	94.6	92.4	93.5
Aizawl	400.3	77.4	+22.92	1,009	98.1	97.7	97.9

TABLE 1.3 DISTANCE FROM THE NEAREST EDUCATIONAL FACILITY

Percent distribution of sampled villages by distance from the nearest educational facility, Mizoram, 2012-13

Educational facility	Within village	Distance from the village			Total percent (100%)
		< 5 km	5-9 km	10+ km	
Primary school	95.1	2.7	1.1	1.1	100.0
Middle school	90.8	5.4	2.2	1.6	100.0
Secondary school	52.8	7.4	6.3	33.5	100.0
Higher secondary school	10.3	4.1	3.9	81.3	100.0
College	2.0	3.3	2.0	91.8	100.0
Madrassa	8.3	0.0	0.0	91.7	100.0

Note: Distance from the village is calculated for only those villages which do not have the facility within the village.
Note: Table is based on unweighted cases.

TABLE 1.4(a) DISTANCE FROM THE NEAREST HEALTH FACILITY

Percent distribution of sampled villages by distance from the nearest health facility, Mizoram, 2012-13

Health facility	Within village	Distance from the village ¹			
		Within 3km	Within 5km	Within 10km	More than 10km
Sub Health Centre	65.8	72.8	75.5	83.2	14.7
Primary Health Centre	15.8	28.3	30.4	39.7	61.4
Community Health Centre	2.7	37.0	37.0	40.2	59.8
District/Govt. Hospital	1.6	14.7	14.7	15.8	85.9
Government Dispensary	0.5	37.0	37.0	38.0	62.5
Private Clinic	2.2	32.6	33.2	35.3	64.7
Private Hospital	0.5	37.0	37.0	38.0	62.5
AYUSH Health Facility ²	1.1	63.0	63.0	64.1	36.4

¹ Including facilities within village.
² AYUSH-Ayurveda, Yoga and Naturopathy, Unani, Siddha and Homeopathy

TABLE 1.4(b) Programmes beneficiaries

Percentage villages having any beneficiaries from selected programs , Mizoram, 2012-13

Programmes	Percentage of villages	Number of villages
Janani Suraksha Yojana (JSY)	66.3	122
Janani Shishu Suraksha Karyakram (JSSK)	21.2	39
Integrated Child Development Scheme (ICDS)	81.0	149
Total number of villages		184

Table 1.5 REASONS FOR DROPPING OUT OF SCHOOL

Percentage of household population aged 6 to 17 years who dropped out of school by main reasons, Mizoram, 2012-13

Reason	Total			Rural			Urban		
	Male	Female	Total	Male	Female	Total	Male	Female	Total
School too far	3.6	3.3	3.5	4.7	4.9	4.8	1.3	0.0	0.6
Further education not necessary	4.7	7.0	5.9	6.3	6.9	6.6	1.4	7.3	4.4
Required for work in household activities/ farm family/business	7.2	6.6	6.9	7.6	6.9	7.3	6.2	6.0	6.1
Required for outside work	12.3	8.9	10.5	7.9	7.9	7.9	21.6	10.8	15.9
Not interested in studies	34.8	28.6	31.6	37.5	25.5	31.4	28.9	34.8	32.0
Cost too much	11.6	11.1	11.3	13.4	14.5	13.9	7.6	4.2	5.8

**Unweighted cases.

TABLE 1.6(a) HOUSING CHARACTERISTICS AND HOUSEHOLD ASSETS

Percent of households by housing characteristics and household assets goods, by residence, Mizoram, 2012-13

Housing characteristics	Total	Residence	
		Rural	Urban
Electricity			
Having electricity	89.7	78.8	99.5
Source of drinking water			
Improved source ¹	83.7	71.8	94.4
Sanitation facility			
Improved sanitation ²	86.4	76.6	95.2
Fuel used for cooking			
Liquefied Petroleum Gas (LPG)	52.0	21.0	79.9
Electricity	0.5	0.3	0.6
Kerosene	1.2	0.5	1.9
Wood	45.5	77.8	16.4
Others	0.0	0.0	0.0
Type of house			
Kachha	20.0	33.4	8.0
Semi - pucca	53.3	51.1	55.2
Pucca	15.7	3.8	26.4
Number of rooms			
1	6.4	8.7	4.3
2	40.4	45.8	35.6
3+	53.1	45.5	60.0
Household assets			
Radio/transistor	9.8	14.0	5.9
Television	73.6	58.0	87.5
Computer/ laptops without internet	11.1	4.0	17.4
Computer/ laptops with internet	6.3	1.0	11.1
Telephone only	3.8	2.0	5.4
Mobile only	86.1	76.3	94.9
Washing Machine	36.0	16.9	53.1
Refrigerator	52.3	32.6	69.9
Sewing machine	31.0	19.7	41.2
Watch/ clock	83.0	77.0	88.4
Bicycle	3.1	2.9	3.3
Motor cycle/ scooter	20.3	11.0	28.7
Car / Jeep/van	10.2	4.6	15.3
Tractor	0.4	0.2	0.5
Water pump/tube well	2.6	0.5	4.5
Cart driven by animal	0.1	0.2	0.1
Cart driven by Machine	0.1	0.1	0.1
Other cart	0.7	0.8	0.5
Cooler/AC	0.2	0.0	0.4
Number of households**	8,583	4,986	3,597
**Unweighted cases. ¹ Includes piped into dwelling piped to yard/plot, public tap/stand pipe/hand pump,/tube well/ bore well/well covered/spring tanker, cart with small tank and bottled water.			

TABLE 1.6(b) HOUSING CHARACTERISTICS BY DISTRICT

Percentage of households with selected characteristics by district, Mizoram, 2012-13

Districts	With electricity	Improved source of drinking water ¹	Improved access to Sanitation ²	Using Liquefied Petroleum Gas	Living in <i>pucca</i> house	Having BPL card
Mamit	88.9	62.6	87.4	29.2	4.6	37.6
Kolasib	96.2	83.9	83.4	54.5	15.0	32.2
Aizawl	100.0	95.2	97.1	79.7	37.8	17.2
Champhai	99.8	92.6	94.6	33.1	7.6	33.9
Serchhip	99.7	91.4	89.0	38.8	9.7	22.7
Lunglei	88.5	80.9	83.2	46.8	9.0	32.6
Lawngtlai	36.0	53.1	46.2	26.7	6.9	32.3
Saiha	89.3	89.9	93.3	58.8	16.1	38.3
DLHS-4	89.7	83.7	86.4	52.3	15.8	29.0
DLHS-3	92.4	76.2	98.1	36.5	7.0	38.5

¹ Includes piped into dwelling piped to yard/plot, public tap/stand pipe/hand pump,/tube well/ bore well/well covered/spring tanker, cart with small tank and bottled water. ² Household having access to toilet facility = improved source of sanitation + flush not to sewer/septic/pit/twin pit + pit without slab + dry toilet.

TABLE 1.7 HOUSEHOLD CHARACTERISTICS

Percentage of the households by selected characteristics of the household head, household size and residence, Mizoram, 2012-13

Characteristics	Total	Residence	
		Rural	Urban
Sex			
Male	81.8	85.8	78.1
